

biopsy in our patients did not show evidence of Crohn's disease, but there was unequivocal evidence of Crohn's disease elsewhere. Furthermore, the failure of symptoms in patients who do not smoke to respond to treatment suggests peptic ulceration associated with Crohn's disease. Treatment with omeprazole led to prompt relief of symptoms and complete healing of ulceration, which was confirmed by endoscopy.

Omeprazole is effective in resistant peptic ulceration,³ but there is only one report of its use in Crohn's disease.⁴ A proton pump inhibitor, it is capable of maintaining high intragastric pH for long periods.⁵ Its effectiveness in our two patients suggests that duodenal ulceration in Crohn's disease is dependent on acid. If prolonged active ulceration can cause pyloric stenosis then intermittent omeprazole treatment might prevent this complication in patients with Crohn's disease. Our

observations support the view that inhibition of acid production is more likely to heal duodenal ulceration associated with Crohn's disease than steroid treatment, which may lead to complications such as perforation or haemorrhage.

Many patients with the irritable bowel syndrome have frequent and urgent defecation that they describe as diarrhoea. Frequency and urgency can be due to an irritable rectum, as in ulcerative proctitis,¹ and patients with these complaints may have normal gut transit times. These patients might be said to have "pseudodiarrhoea" (faecal frequency without diarrhoea). True diarrhoea entails rapid transit through the intestine, but transit time is not measured routinely in clinics and until recently there were no accurate ways of doing so.^{2,3} As different treatments are appropriate for patients with fast, normal, and slow transit a simple method of measuring transit in the outpatient clinic would be valuable. Davies *et al* found a close correlation between whole gut transit time and stool form scored on an eight point scale, but they studied motivated volunteers and a scientific observer examined the stools.⁴ We investigated whether a simple record of stool form kept by the patient could be used as a guide to intestinal transit rate in the irritable bowel syndrome.

Patients, methods, and results

We devised a seven point scale in which stools were scored according to cohesion and surface cracking: 1, separate hard lumps like nuts; 2, sausage shaped but lumpy; 3, like a sausage or snake but with cracks on its surface; 4, like a sausage or snake, smooth and soft; 5, soft blobs with clear cut edges; 6, fluffy pieces with ragged edges, a mushy stool; 7, watery, no solid pieces.

We recruited 30 consecutive patients (10 men, 20 women; ages 18-68) from a general gastroenterology outpatient department. All fulfilled the diagnostic criteria for the irritable bowel syndrome⁵ and consented to the study. Each patient was given a form to record the type and time of evacuation of six consecutive stools and to indicate whether the desire to defecate was urgent. The mean score for the six defecations was calculated for each patient. Whole gut and regional colonic transit times were measured simultaneously: patients swallowed 20 radio-opaque polyethylene markers on four consecutive mornings, and an abdominal radiograph was obtained on the fifth morning. Whole gut transit time was calculated as 1.2

times the number of markers in the abdomen and regional transit time as 1.2 times the number of markers in the region.³ In one patient with slow transit radiography was repeated on the sixth morning.

Whole gut transit time ranged from six to 108 hours. Stool frequency ranged from 0.3 to 5.0/24 h. There was no relation between stool frequency and whole gut transit time ($r = -0.022$). The mean stool form score was evenly distributed, with similar numbers of patients scoring <3, 3-5, and >5. Mean stool form score correlated well with whole gut transit time ($r = -0.77$, $p < 0.001$; figure). Although there were

Relation between mean stool form score (1=hard lumps, 7=watery; see text) and whole gut transit time in patients with irritable bowel syndrome ($r = -0.77$, $p < 0.001$)

significant correlations between regional colonic transit time and mean stool form score, no area of the colon was particularly associated with stool form (right colon, $r = -0.43$, $p < 0.05$; left colon, $r = -0.62$, $p < 0.01$; sigmoid and rectum, $r = -0.54$, $p < 0.01$). Urgency was recorded at least once by 22 patients. Urgency was associated with looser stools (χ^2 for trend=26, $df=1$, $p < 0.001$), but the frequency of defecation was the same in patients with and without urgency (median frequency=1.6 v 1.9/24 h; $p=0.8$, Mann-Whitney U test).

Comment

We found that patients with the irritable bowel syndrome can keep meaningful records of stool form and that these are a reasonable guide to whole gut

transit time. In patients with formed stools (scores 1-4) and normal or slow transit frequent defecation and urgency are actually pseudodiarrhoea, presumably due to an irritable or hyperreactive rectum, and constipating agents should be avoided. As patients with slow and fast transit may respond differently to high fibre diets and bulking agents, respectively, perhaps they should be asked to record their stool form so that the doctor can assess the transit rate and plan treatment.

Cervical intraepithelial neoplasia is common in young symptomless women. Such women often believe that the function of a smear test is to detect cancer rather than to prevent it.¹ Insensitive postal notification of abnormal results can cause unnecessary fear and add to the negative aspects of a mass screening programme.^{2,3}

We carried out a controlled trial to assess women's anxiety and beliefs about their health when a smear test showed dyskaryosis and to evaluate the effectiveness of a personal leaflet sent with postal notification of the result of such a test.

Patients, methods, and results

Women due to attend the University Hospital of Wales because a cervical smear test had shown dyskaryosis were randomly assigned to one of two groups. The first group (31 patients) received a standard computerised letter, which read: "Your recent smear test showed slight abnormality. Please could you attend the cytology clinic at... for a repeat test and further advice." The second group (29 patients) received a leaflet and a more personalised letter stating, "Your recent smear test showed slight abnormality which need cause you no anxiety. Please read the enclosed leaflet carefully, you will find it helpful and reassuring. Please could you attend the cytology clinic at... on..." The main message in the leaflet was that most smears showing dyskaryosis do not indicate cervical cancer. All patients were interviewed during the consultation by the examining doctor (CW), who used a structured questionnaire. Information collected comprised sociodemographic data, psychiatric history, the women's perceptions of the meaning of the result of their smear test, and their perceptions of their health after receiving the result. They were asked who they had chosen to discuss the result with and whether they had sought professional advice before their appointment. Differences between the two groups were measured by comparing the women's beliefs about their health as measured by the questionnaire and their levels of anxiety before and after consultation as assessed with the Spielberger state-trait anxiety inventory.⁴

Nineteen women who did not receive a leaflet thought that they had cancer compared with only one of the women who did receive a leaflet ($\chi^2=22.56$, $df=1$, $p<0.001$). Twelve of the women not sent a leaflet thought that their health had deteriorated on receipt of the result compared with two who were sent a leaflet ($p<0.01$; Wilcoxon matched pairs signed ranks test).

The group who were not sent a leaflet had a significantly higher initial state anxiety level than the group who were ($p<0.0001$). State anxiety levels after consultation and trait anxiety levels were not significantly different between the groups (table).

Anxiety scores of patients who had received letter, with or without reassuring leaflet, informing them that cervical smear test showed dyskaryosis

Mean Spielberger state-trait inventory scores (scale 20-80)	Group not sent leaflet (n=31)	Group sent leaflet (n=29)	Difference between means (95% confidence interval)
State anxiety levels:			
Before consultation*	49.59	39.00	10.59 (5.8 to 14.8)
After consultation	33.35	32.21	1.14 (-3.4 to 5.7)
Trait anxiety level†	40.81	37.21	3.60 (-7.6 to 0.4)

*State anxiety is a measure of transitory emotional state characterised by subjective feelings of tension and heightened autonomic nervous system activity.

†Trait anxiety is a measure of relatively stable individual differences in anxiety proneness.

Comment

Our study highlights the fact that precancer is a concept that women find difficult to understand. The term implies early cancer to most women, and a new term—for example, "early warning cells"—would seem more appropriate. The mean level of anxiety before consultation in the women not sent a leaflet was similar to that provoked by very stressful situations, while the mean in the group sent a leaflet was similar to that expected for general medical and surgical outpatients.⁵

Evidence suggests that investigation and treatment of cervical intraepithelial neoplasia is psychologically traumatic.⁵ Good education and counselling from the onset may prevent future psychiatric and psychological morbidity and improve compliance with treatment. A questionnaire sent to all health authorities in Wales in September 1988 showed that, although seven of nine health authorities sent educational leaflets with cervical cytology call and recall letters, only one sent leaflets when notifying women of normal or abnormal results of smear tests. Our study suggests that these leaflets should be sent with notification of abnormal results.

We thank Professor Nigel Stott and Dr Roisin Pill, department of general practice, University of Wales College of Medicine, and Dr Tim Peters, department of medical statistics, University Hospital of Wales, for help with design and analysis; Mrs Penny Moore for typing the manuscript; and Pfizer for financial help.
