A possible link between hyperinsulinaemia or insulin resistance and hypertension is currently debated. Recent evidence suggests that patients with essential hypertension are insulin resistant^{1,2} and that hyperinsulinaemia is associated with raised blood pressure in subjects with normal glucose tolerance.³ Insulin enhances sodium reabsorption from the renal tubules and stimulates the activity of the sympathetic nervous system.⁵ Nevertheless, it is yet unknown whether hyperinsulinaemia itself is causally related to increased blood pressure or is merely the consequence of insulin resistance in hypertensive patients. This study was designed to evaluate the relation between serum insulin concentration and blood pressure in non-obese patients with insulinoma in order to study the effect of chronic hyperinsulinaemia on blood pressure.

Patients, methods, and results

We evaluated data obtained from eight Japanese patients with insulinoma (six women and two men, mean (range) age 41 (24-56), mean (range) body mass index 22.5 (21-25) kg/m²) admitted to Hirosaki University Hospital during 1973-89. The mean duration of the disease was assumed to be 34.8 (range 2-62) months, estimated from the time of appearance of the first hypoglycaemic symptom(s). The diagnosis of insulinoma was confirmed by histological examination of the resected insuloma in all patients. The renal, hepatic, and cardiac functions of the eight patients were all within normal ranges. Two patients had a familial history of hypertension and the remaining six did not. Ninety three non-obese subjects (45 women and 48 men, mean (range) age 48 (20-65), mean (range) body mass index 23.2 (18-26) kg/m²) with normal glucose tolerance, according to the World Health Organisation criteria, served as controls.

We compared, firstly, the blood pressure of the patients with insulinoma with that of the controls and, secondly, blood pressure, and serum insulin and fasting plasma glucose concentrations before and after resection of the insulinoma. Blood pressure was measured in the supine position at 8 00 am and fasting

serum insulin and plasma glucose concentrations at least three times in each patient both before and 1-2 months after the operation. Differences in the values were tested by Wilcoxon's rank sum test or Wilcoxon's signed rank test, when appropriate. Correlation between the serum insulin concentration and mean blood pressure was evaluated by Spearman's rank correlation coefficient. A p value less than 5% was considered significant.

Neither the systolic nor diastolic blood pressure before operation in the patients with insuloma was higher than in the controls (table). The resection of the insulinoma caused a significant fall in serum insulin concentration and an increase in plasma glucose concentration but did not lower blood pressure. There was no significant correlation ($r_s=0.030$) between the serum insulin concentration and mean blood pressure in the patients.

Comment

Insulin is considered to have a role as a pressor factor.^{4,5} Nevertheless, blood pressure in our patients with insulinoma, who were assumed to be sensitive to insulin, was not higher than in the controls and was not reduced after resection of the insulinoma. These results suggest that hyperinsulinaemia in patients with insulinoma is not associated with increased blood pressure. The precise reason(s) for the lack of association between serum insulin concentration and blood pressure in our patients is unclear. The period of hyperinsulinaemia in the patients with insuloma might have been too short for a change in blood pressure to develop compared with that experienced by hypertensive patients. Although the results obtained from this small number of patients need to be interpreted with caution, the observations imply that a few years of hyperinsulinaemia itself may not increase blood pressure in non-obese subjects with normal kidney function, and this deserves further investigation.

Correction

Respiratory symptoms and atopy in Aberdeen schoolchildren: evidence from two surveys 25 years apart

An authors' error occurred in this paper by Titus K Ninan and George Russell (4 April, pp 873-5). In the abstract, the number of participants in 1989 should read 4003 (not 3942 as published); this number also applies in paragraph 4 of the materials and methods section and in the first paragraph of the results section. The percentage of questionnaires completed (paragraph 4 of methods section) becomes 85.0% (3403/4003).

Geometric mean of serum insulin and blood pressure concentrations (95% confidence interval) in eight patients with insulinoma before and after operation and controls

	Patients with insulinoma		Controls
	Before operation	After operation	
Fasting serum insulin (pmol/l)	159 (121 to 196)*	66 (39 to 92)	65 (58 to 69)
Fasting plasma glucose (mmol/l)	2.6 (2.1 to 3.1)*	5.1 (4.8 to 5.4)	5.4 (5.2 to 5.5)
Systolic blood pressure (mm Hg)	117 (106 to 127)	130 (121 to 138)	124 (121 to 126)
Diastolic blood pressure (mm Hg)	69 (62 to 75)	78 (70 to 85)	77 (74 to 79)
Body mass index (kg/m ²)	22.5 (21.0 to 23.9)	21.4 (19.9 to 22.8)	23.2 (22.5 to 23.7)

*p<0.05 Compared with controls and patients after operation.
