Personal computer software for handling references from CD-ROM and mainframe sources for scientific and medical reports

Richard G Jones

Most practising medical scientists are now familiar with the use of computer based literature searches as a preliminary source of data in a programme of research. For most the searches will probably have been conducted by a library assistant skilled in the use of medical databases.¹⁻⁴ Of late, access to data sources such as MEDLINE, either through mainframes or from CD-ROMs, has become easier, and more people are now able to conduct their own searches.^{2-5,7} Whatever the method used a persistent problem has always been how to handle the large volume of data generated. If results are provided on paper they are difficult to organise systematically and often require repeated retyping and refiling in manual systems.

The inefficiency of such an approach becomes most obvious in writing papers or completing theses, when the relevant references must be painstakingly and accurately recompiled in the new manuscript, taking account of the lack of standardisation in journal requirements. Indeed compiling and formatting the bibliography of a thesis must class as one of the most soul destroying undertakings of a scientific training. Help is now at hand, however, in the form of a number of excellent packages for personal computers, which help in storing and organising references and also the automatic compilation of bibliographies formatted in appropriate styles (appendix 1).⁸⁻¹² Furthermore these packages can accept data directly from mainframe and CD-ROM sources, thus enabling a seamless cycle from database search through assimilation to the referencing of a new scientific manuscript.

I describe here the components of the process and the links between them and will briefly review a selection of the packages available.

Data sources

There are many available data sources of medical reports (table). The two most widely used databases

are MEDLINE and Excerpta Medica. These databases are updated by their owners each month with new medical publications and are then made available to users. Access can either be online to a mainframe host computer or through a locally held CD-ROM version of the database.^{2,13} The mainframe host computer will update its database continually, and users gain direct access to the database via telephone networks and pay for time spent connected to the database. CD-ROM versions are copies of the main database made periodically (say every three months) and sold to end users, who pay a yearly subscription. Once the user (usually a library) has bought the CD-ROM it can be accessed at no further cost, via a CD-ROM drive attached to a personal computer. In both cases the database may be available from a number of different information vendors, each of whom, though supplying the same basic data, may offer it with other services and facilities. Alternative sources include the disk based version of *Current Contents*, which is issued weekly and is provided with its own retrieval software.

For some years the Swiss company Radio-Suisse has

Examples of some available databases and sources

Database name	Description	Hosts
Biosis Previews	Major database on biological sciences	Datatar, DIALOG, ESA-IRS
Excerpta Medica	Major medical database biased towards drugs and European publications	Datatar, DIALOG
Martindale	Pharmacopoeia online	Datatar, DIALOG
MEDLINE*	Index Medicus plus abstracts, overlaps by only 30% with Excerpta Medica	Datatar, DIALOG, BLAISE-LINK
Toxline	Big toxicology database has about 12 000 new records a month	Datatar
Current Contents	Floppy disk format, includes database search facility	Floppy disk

Department of Chemical Pathology and Immunology, University of Leeds, Leeds LS2 9JT
Richard Jones, senior lecturer

BMJ 1993;307:180-4

been a leading supplier of information in Europe offering both MEDLINE and Excerpta Medica in its DataStar service. In the United States the National Library of Medicine has been a major host supplier. Other suppliers include Maxwell Online, through the BRS Colleague service, which is available internationally via a network of host systems (appendix 2).¹⁴ The choice of vendor is determined on the basis of ease of access, cost, and the range of services.¹ The latter may include help systems, user friendly search languages, and, in the case of some systems, direct access to full text databases of leading journals such as the *Lancet*, and *New England Journal of Medicine*, and *BMJ*.¹⁵ Costs are incurred in a number of ways with these systems and tend to rise in proportion to the number of facilities. They include telephone charges for dial up access by using modems, network charges when using systems such as DialPlus (BT), connect time fees, and charges for accessing, printing, and downloading citations identified in the searches. For academics access via academic networks (in the United Kingdom JANET) can offer substantial savings as telephone and network charges are underwritten centrally.

The choice of CD-ROM supplier is made on similar grounds of cost and availability but is also likely to be influenced by the questions of hardware support and access to other CD-ROM titles such as atlases, encyclopaedias, and medical texts such as the *Oxford Textbook of Medicine* or the *Multi-media Encyclopaedia of Mammalian Biology*.

MAINFRAME V CD-ROM

The choice between the mainframe or CD-ROM as primary source is likely to be influenced by several other factors. At present CD-ROMs have limited capacity: five years of data fill three disks. Therefore extended searches can be accomplished only by swapping disks, unless a CD-ROM jukebox is available. If such searches are needed regularly online access may be preferable. Similar arguments exist regarding disk based issues of *Current Contents*, where, though individual disks contain current information, searching in depth is difficult. The mainframe systems tend to be faster than the CD-ROM, especially for complex searches. Furthermore, the updates to the CD-ROMs tend to lag the mainframes by about three months, so if up to the minute information is required online access is preferable.

CD-ROMs do have several potential advantages.⁶ Because connect time is inexpensive (and usually free) more time can be spent browsing the system, unexpected references often being found which might have been missed with a mainframe search limited by time. Similarly, searches can be constructed iteratively, and this can help to increase the yield of useful data. The human-computer interfaces of personal computer systems also tend to be better designed and therefore easier to use than those on the mainframe systems and include a greater depth of help for the construction of complex searches. This can be a great advantage to infrequent users as the programmes can usually be run without extensive training and the skills relearned more easily. Finally there is no need to understand computer communications before being able to contact the database.

Modems, network gateways, and communications software can present a very intimidating and frustrating barrier for a beginner with no desire to become a computer "hacker." A recent survey identified that up to 11% of searches proved unproductive because of system or telecommunications failures,¹⁶ a figure which for most new users would be unacceptable.

TRANSFERRING FILES

Whichever mechanism of searching is chosen the

Features of bibliographic databases for personal computers

- Electronic storage of references
- Annotation of references
- Sorting and selection by using keywords, authors, dates, etc
- Importation of references from mainframe/CD-ROM data sources
- Automatic generation of bibliographies

end result will be a list of references with or without their abstracts. In the past this usually took the form of a printout, which for big searches could run to several pages. Though useful as a list for finding references in the library, any further use of the references—for example, for inclusion in a reading list or bibliography—required them to be laboriously retyped. With the advent of bibliographic databases on personal computers it is now usual for the list to be available as a file which can be transferred from the host system, whether CD-ROM or mainframe, on to the personal computer.¹⁵ At their simplest these files can be handled by standard word processors and can be edited or reorganised before printing. Once on the personal computer, however, the files can then be read by the bibliographic systems and the data incorporated into the owner's own local database. This not only obviates the need for retyping but also allows many other features of the bibliographic systems to be used.

Bibliographic systems

The available systems have evolved over the past decade in parallel with the increasing availability of personal computers. They have largely originated as programs developed by practising scientists or librarians and provide many facilities well adapted for academic use. Indeed, most of the available systems provide comprehensive database functions to facilitate and support scientific use of the literature (see box). These include the ability to reindex retrieved references, to sort and search selectively through them, and, in most cases, to add extensive notes for storage within the database. In addition, some systems allow indexing of reprint collections and some even automatically print reprint request cards for dispatch to the appropriate author.

Such features can be exploited for many different purposes beyond the maintenance of a personalised database of the literature. When run on local area networks many users can share the same database, allowing small research teams to maintain a common bibliographic source, which can facilitate interaction and reduce fruitless repetitive searching. Similarly, such shared access can be used to support teaching by allowing access by students to appropriately constructed databases. At the other extreme the database managers can be run on notebook sized portable personal computers and carried into libraries, where notes can be edited directly onto the database.

Bibliography generation

By far the most time saving feature of these systems, however, is their ability to generate correctly sequenced and formatted bibliographies for scientific papers.⁸ A draft word processed manuscript can be scanned by these systems to identify the citations it contains. These can then be retrieved from the database, formatted, and tailored as required for particular journal or book (fig 1).

FIG 1—Complete process of transferring references from online or CD-ROM sources through personal computer databases and into finished manuscripts

FEATURES

The method of incorporating citations into the draft manuscript entails linking the citations in the text with the references in the database. Most systems give each reference a unique identification number or code within the database (fig 2 shows examples). This identifier is placed within the text at the relevant citation point. Once the draft manuscript is complete a program is run which reads these identifiers, extracts the references from the database, and compiles them into a bibliography. The format of the references in the latter can be automatically adjusted to that required by the journal for which the manuscript is intended (figs 3a and 3b). At the same time the identifiers in the draft manuscript are updated to the format required for the final document (fig 4). These might be in numerical

FIG 3—Two examples of same references automatically generated in styles appropriate for different journals. (a) Formatted for "Journal of Comparative Neurology," (b) Formatted for "Clinical Chemistry"

or the more traditional "author, date" style, and formatting controls such as superscripts can be automatically applied for the most widely used word processors. Should there be a need to resubmit a paper to a different journal at a later date a new bibliography in a completely different format can be generated without the need for retyping by simply repeating the process but using the new target style. Similarly, if references are to be added or deleted this can be done without the need to readjust manually identifiers and bibliographies.

The sophistication of the available personal computer packages varies considerably, reflecting the different degrees of commercial redevelopment of the original systems. Though all provide basic facilities, some offer features which considerably enhance their use.^{9 10 15} Some are able to scan manuscripts, compiling bibliographies on the basis of free text entries in—for example, author, year format. This obviates the need to enter unique identifiers, but manual selection and confirmation and selection of database entries may be necessary. Similarly the flexibility in relation to the

While there is some controversy on this point (1) most authors feel that the traditional methods are still valid (2, 3).

FIG 4—Examples of different styles of citation markers which can be automatically generated by these programs. (a) Formatted for "Journal of Comparative Neurology," (b) Formatted for "Clinical Chemistry"

formats of the generated citation styles is greater with some packages than with others. For example, while all support numbered (for example, (1)) and author and year (for example, (Smith *et al*, 1982)) styles some allow extra formatting control including subscripts and superscript and the ability to include page numbers (for example, (Smith *et al*, 1982; 27p)). Some even provide the ability to control the order of citations within a group—for example, alphabetical (Jones, 1985; Smith, 1987; Zieve, 1982) or chronological (Zieve, 1982; Jones, 1985; Smith, 1987). The cost of increased flexibility, however, is usually complexity of use, and for general users a compromise between adequate functionality and ease of use must be made.

Most systems are fully compatible with the more popular word processors—for example, Microsoft Word, Wordperfect, Wordstar. By the use of small "terminate and stay resident" programs some can be fully integrated with these word processors and can be run simultaneously. These programs are run just before running the word processors and lie dormant in memory until activated by a unique keystroke sequence—for example, Control-Alt-r. The word processor can then be run to allow normal text editing to proceed. At points where citations are required the citation program can be activated. Once activated the program appears on screen as a pop up window overlaying the word processing screen. Direct access to the reference database is then possible while the text of the manuscript is still visible on the screen. References can then be scanned within the database so that searches can be made to find appropriate sources. Once found the unique citation identifiers can be automatically inserted into the manuscript before control is returned to the word processor. This avoids the need to be constantly swapping between programs and makes the process of referencing a manuscript almost painless.

CHECKLIST

Given the range of available packages and their varying degree of sophistication and cost how does one choose between them? The box provides a check list of

Ten key questions to ask when selecting a system

- 1 Is it compatible with my word processor?
- 2 Will it coexist with my word processor as a terminate and stay resident program?
- 3 Will it automatically generate bibliographies in the styles I need?
- 4 Can the system import from major reference sources?
- 5 Will it allow customisation of import and export formats?
- 6 Is it easy to use?
- 7 How good is the user manual?
- 8 What mechanism of linkage does it use between the manuscript and the database?
- 9 Will it support group usage?
- 10 How much does it cost to get all the features I need?

10 basic features which can be used to examine and compare the systems. The relative importance of each feature will differ depending on the intended use and the ability of the user. Novice users may prefer menu driven systems which could infuriate the experienced computer buff. Similarly for group work network compatibility might be an important and overriding factor. As a minimum packages should be capable of importing data from the main reference sources (for example, MEDLINE), they should be able to read manuscript files in the format of the user's word processor, and they should be able to produce citation marks in both numeric and author, year formats and bibliographies in styles suitable for relevant major journals, including Vancouver style.

As essential as the word processor?

Does the use of these packages improve the quality of the finished manuscripts? The simple answer must be no. The fundamental requirements of good papers remain the same: solid science, clear thinking, well written prose, high quality informative illustrations, and scholarship. Indirectly, however, these systems can help. They alleviate many of the chores, allowing authors to concentrate more on content. They encourage selective and systematic use of published reports and from the editor's point of view must help in eliminating detailed errors in format and content of bibliographies.

Do they aid clinical decision making? Again the answer may be no, though this may be because to date access and appropriate training has been lacking.^{3,17} In a period when time is becoming ever more scarce their use to support research and clinical practice is likely to become commonplace and, dare I say, as essential as that of the word processor.^{3,18}

This article was prepared at the request of the scientific developments subcommittee of the Association of Clinical Biochemists, but the views expressed are mine. I thank all the software suppliers who provided the packages included in this review and Maxwell Online for free access to Colleague. I am grateful for the helpful comments of the scientific developments subcommittee of the Association of Clinical Biochemists and Dr Julian H Barth.

Appendix 1

Some available microcomputer packages

The list includes systems advertised in major scientific journals or known to be in widespread general use. All suppliers who were invited to submit packages did so and provided excellent support.

Pro-Cite

Personal Bibliographic Software Inc, 535 Avis Drive, Suite 10, Ann Arbor, Mississippi 48108, United States.
Tel +1 (313) 996-1580
Cost £300

Pro-Cite is a professional bibliographic system available for both IBM compatible personal computers and Macintosh. It is part of a family of products, PRO-SEARCH and BIBLIO-LINKS, which support mainframe searching and downloading. It is enormously flexible, being configurable to store any information which could be conceivably required in a bibliography, including books, chapters, papers, personal communications, reports, and even slides. The downside of the flexibility is that the interface is fairly complex and could be confusing for casual users. The linkage packages for importing references are not included in the basic price.

Papyrus

Research Software Design, 2718 SW Kelley St, Suite 181, Portland, Oregon 97201, United States.
Tel +1 (503) 796-1368
Cost £99

Papyrus is a very powerful and cost effective bibliographic system. It is flexible and configurable and can accommodate a

wide variety of sources of material including audiovisual material and slides. The user interface is a little idiosyncratic and it requires more skill to run than do some other systems. It is fully compatible with PRO-CITE and offers an alternative of similar specification. A comprehensive and easy to use manual is provided.

Endnote

Cherwell Scientific Publishing, 27 Park End Street, Oxford OX1 1HU.
Tel 0865 784800
Cost £114

Endnote is a single user bibliographic database available on IBM and Macintosh systems. It is fully menu driven by using standard windowing techniques. Though not as powerful as some of the more expensive systems, it is easy to learn and offers facilities which would more than satisfy most users. To incorporate references from online systems a companion package ENDLINK is required, which is an extra cost. This was not available for review. The manual is clear and well presented. In summary, an attractive and easy to use package.

Paperbase Deluxe

Wight Scientific, 44 Roan Street, London SE10 9JT.
Tel 081 858 2699
Cost £90

Paperbase Deluxe is the product of several years of development of a bibliographic system designed by an active research worker. Though lacking some of the sophistication of the more expensive products it functions adequately and is well supported by the supplier. The main weakness of the review copy was the user interface, but the newly revised data editor suggests that this will soon be radically improved. As Paperbase is in a continual process of development, with upgrades available to users at nominal cost, it offers a low cost solution for individual users.

Reference Manager

Research Information Systems Inc, Bilaney Consultants Ltd, St Julians, Sevenoaks, Kent TN15 0RX.
Tel 0732 450002
Fax 0732 450003
Cost £300

Reference Manager is a mature commercial system well adapted to medical science. The interface is menu driven with clever use of windowing techniques to support most functions. It is extremely powerful with good database functions and scope for extensive customisation. It comes configured for use with all the major sources of bibliographic information. It has some limitations in respect of the reference types it can store (for example, slides, patents) but compensates for this through its ease of use. It supports terminate and stay resident integration with popular word processors such as Word-perfect and Microsoft Word. A Windows version is available.

Autobiblio

Biosoft, 22 Hills Road, Cambridge CB2 1JP.
Tel 0223 68622
Fax 0223 312873
Cost £125

Available for Macintosh only. Not reviewed but system description seems comprehensive.

Refsys Super

Biosoft, 22 Hills Road, Cambridge CB2 1JP.
Tel 0223 68622
Fax 0223 312873
Cost £125

A fairly simple system from Biosoft. It is easy to use with a convenient built in manual available on a series of help screens. It lacks the sophistication of other packages, particularly in relation to its handling of keywords. The automatic bibliography generation function is cumbersome, requiring more manual editing than should be necessary.

Appendix 2

Sources for major databases

Neuroleptics, learning disability, and the community: some history and mystery

David Manchester

Recent papers have again highlighted the consistently high use of neuroleptic agents among people with a learning disability, despite the lack of good evidence to support their role in this population for behaviour management and despite the risks of such medication. Evidence suggests, however, that prescribing habits have remained relatively unchanged; the reasons for this are poorly understood. Given the lack of understanding about the factors contributing to such drug use, and the possibility that use of neuroleptics will increase as people with learning disabilities move into the community, there seems a clear need for clinical guidelines to cover the prescribing and monitoring of neuroleptics within this group. Such guidelines should also ensure that reviews, using reliable measures of treatment efficacy, are carried out regularly.

For the sake of clarity the term learning disability is used throughout this paper and replaces the various other terms (for example, mental handicap, mental retardation, and developmental disability) used to describe the same client population in some of the papers mentioned.

Behavioural medication and learning disability

Several recent studies in Britain and abroad have again attested to the widespread use of psychotropic medication in people with learning disabilities.¹⁻⁴ It is

estimated that most people with a learning disability receive one or more drugs to control behaviour, including stimulants, anticonvulsants, antidepressants, major tranquillisers, and anxiolytics.⁵ Overall, those most commonly used in managing behaviour are neuroleptics. In a recent review of 168 people with learning disabilities living in hospital, 49% were receiving neuroleptic medication.³

Standard psychopharmacology text books assert that the clearest indication for the use of neuroleptic medication is to treat psychiatric disorders, where the symptoms they aim at decreasing are causing suffering and disability for the client.⁶ Estimates for serious psychiatric disorders in people with learning disabilities range from 8% to 15%.⁷ One recent American survey of over 40 000 people with learning disabilities living in hospital or in the community noted a prevalence for psychoses of 6.68% in people under 22 years of age and of 5.69% in people aged 22 years and over.⁸ The incidence of schizophrenia alone has been estimated as 3.4% among hospital residents.⁹

Although there is a consensus that the prevalence of psychiatric illness in people with learning disabilities is greater than that in the general population, the true rate is notoriously difficult to verify. This is partly because people with severe to profound disability are unlikely to be able to give adequate or reliable self reports, and partly because most studies have concentrated on hospital populations, which are by definition unrepresentative of the client group as a whole. Studies on this topic have also been criticised for using vague
