Abstract

Objectives To assess the ability of patients with binocular 6/9 or 6/12 vision on the Snellen chart (Snellen acuity) to read a number plate at 20.5 m (the required standard for driving) and to determine how health professionals advise such patients about driving.

Design Prospective study of patients and postal questionnaire to healthcare professionals.

Subjects 50 patients with 6/9 vision and 50 with 6/12 vision and 100 general practitioners, 100 optometrists or opticians, and 100 ophthalmologists.

Setting Ophthalmology outpatient clinics in Sheffield.
Main outcome measures Ability to read a number plate at 20.5 m and health professionals' advice about driving on the basis of visual acuity.

Results 26% of patients with 6/9 vision failed the number plate test, and 34% with 6/12 vision passed it. Of the general practitioners advising patients with 6/9 vision, 76% said the patients could drive, 13% said they should not drive, and 11% were unsure. Of the general practitioners advising patients with 6/12 vision, 21% said the patients could drive, 54% said they should not drive, and 25% were unsure. The level of acuity at which optometrists, opticians, and ophthalmologists would advise drivers against driving ranged from 6/9⁻² (ability to read all except two letters on the 6/9 line of the Snellen chart) to less than 6/18.

Conclusions Snellen acuity is a poor predictor of an individual's ability to meet the required visual standard for driving. Patients with 6/9 vision or less should be warned that they may fail to meet this standard, but those with 6/12 vision should not be assumed to be below the standard.

Introduction

Drivers must ensure that their vision is good enough to drive, but people commonly seek the advice of healthcare professionals on this matter. The legal standard required for driving a private car or motorbike (group 1 entitlement) is to be able to read a number plate at 20.5 m. Guidelines issued by the Driver and Vehicle

Licensing Authority suggest that this corresponds to between 6/9 and 6/12 vision on the Snellen chart (Snellen acuity),¹ and the guidelines of the Royal College of Ophthalmologists equate this to about 6/10 vision. However, 6/10 does not exist on standard Snellen charts, and professionals might be led to assume that all those with 6/9 vision meet the required standard and that those with 6/12 do not.

We aimed to determine what percentage of patients with 6/9 and of those with 6/12 vision could pass a number plate test. We then assessed by postal questionnaire the advice given by healthcare professionals.

Participants and methods

Participants

Fifty patients with binocular 6/9 vision and 50 with 6/12 vision were recruited prospectively from ophthalmology clinics. Their ability to read a number plate was tested out of doors at a distance of 20.5 m. Snellen acuity was measured unilaterally and binocularly. We included patients if they could see the full line on the Snellen chart binocularly and no more than two letters on the line below. The patients were given two attempts at reading a standard front number plate (registration number F758 EKY). Some numbers and letter-number combinations are harder to see than others.² The number plate we chose represented a moderately difficult combination. All tests took place between 9 am and 3 pm during good weather. The patients wore their usual glasses, but the accuracy of the refraction of the lenses was not tested. We did not assess visual fields or driving status.

Questionnaires

Questionnaires were sent by post to 100 ophthalmologists throughout Great Britain and 100 optometrists or opticians in South Yorkshire (boxes). A modified questionnaire went to 100 general practitioners in South Yorkshire.

Results

Number plate test

The 6/9 and 6/12 vision groups each comprised 21 men and 29 women, with a mean age of 78 (range 43

Questions to general practitioners

A patient comes to you asking if his or her vision is good enough to drive. You measure the patient's visual acuity as 6/9 on a Snellen chart and ascertain that there are no other reasons to preclude driving (that is, reduction in visual field or diplopia). Would you tell the patient he or she could drive? (Answers: "yes," "no," or "don't know.")
If "no" or "don't know" would you refer to any one else or are there any other tests that you would do or information that you would seek? (Please elaborate.)
If you measure the patient's visual acuity as 6/12 on a Snellen chart and ascertain that there are no other reasons to preclude driving, would you tell the patient he or she could drive?
If "no" or "don't know" would you refer to any one else or are there any other tests that you would do or information that you would seek? (Please elaborate.)

to 95) and 73 (range 18 to 94) respectively. Two patients with binocular 6/9 vision had best unocular acuities of 6/12. In the group with 6/12 binocular vision, five had unocular acuities of 6/9 but managed only 6/12 binocularly and two had unocular acuities of 6/18 but achieved the higher standard binocularly. Thirteen patients (26%, 95% confidence interval 14% to 38%) with binocular 6/9 vision could not read the number plate, including two whose best unocular acuity was only 6/12 and 11 whose vision in the second eye ranged from 6/9 (five patients) to counting fingers.

Seventeen patients (34%, 21% to 47%) in the 6/12 group could read the number plate, including four of the five with a unocular acuity of 6/9. The acuity in the second eye of the 13 others ranged from 6/12 (six patients) to counting fingers

Questionnaires

The response rate was 63% for general practitioners, 60% for optometrists and opticians, and 72% for ophthalmologists. Based on a Snellen acuity of 6/9, 76% of the general practitioners would tell patients that they could drive, 13% would advise against it, and 11% were unsure. Based on a Snellen acuity of 6/12, 21% of the general practitioners would tell patients that they could drive, 54% would advise against it, and 25% were unsure. Of the 18 who were unsure about either question, 94% would refer the patient to either their optician, the guidelines of the Driver and Vehicle Licensing Authority, or the Highway Code.

The table summarises the responses from optometrists and ophthalmologists regarding the level of acuity at which patients are advised that they should not drive. Thirteen (13 of 60; 22%) optometrists advised "borderline" cases to self assess, and nine oph-

thalmologists (9 of 72; 13%) quoted no Snellen acuity but advised self assessment. Of the ophthalmologists mentioning the required standard, four quoted an incorrect distance.

Discussion

The number plate viewed at 20.5 m subtends a visual angle of 13.4 minutes of arc, geometrically corresponding to 6/15 on the Snellen chart. The guidelines linking Snellen acuity and driving come from a statistical model. This was derived by Drasdo and Haggerty on the basis of 28 candidates failing the vision test for driving, whose binocular acuity was correlated with the distance at which they could read a number plate.³ The model estimated that 6/9⁻² (the ability to read all except two letters on the 6/9 line of the Snellen chart) would produce the same failure rate as the number plate test, and some authorities extrapolated this to 6/10. The probability of passing the test with an acuity of 6/7.5 or 6/18 was predicted as 99% and 6% respectively. Our study agrees broadly with this but highlights the difficulties of predicting an individual's chance of success. As our patients had eye disease, they may have performed worse than a normal cohort, where fewer patients might fail with 6/9 vision but more patients might pass with 6/12 vision.

The questionnaire responses showed that drivers receive a spectrum of advice. Establishing a level of Snellen acuity at which to advise patients against driving could represent the upper limit, below which caution is advised, or the lower limit, below which all are advised to stop. Thus none of the responses is necessarily incorrect if accompanied by advice on the legal requirements. However, for patients with binocular Snellen acuity of 6/9 or less inquiring about their eligibility to drive, the only correct response is "I don't know," unless the health professional tests their ability to read a number plate outside.

Surveys have shown that a low proportion of the public know the visual requirements for driving, and other studies have shown that a major proportion of drivers would not pass the number plate test.⁴⁻⁶ The advantage of the number plate test is its amenability, but the practicalities of measuring the distance and self assessing can be off-putting for some. If those testing vision could provide a way for people to self assess—for example, by mounting a number plate at the correct

Cut-off point of visual acuity at which opticians, optometrists, and ophthalmologists would advise patients against driving. Values are numbers (percentages) of healthcare professionals

Snellen acuity	Optometrists and opticians (n=60)	Ophthalmologists (n=72)
6/9 ⁻²	15 (25)	6 (8)
6/10	1 (2)	4 (6)
6/12	15 (25)	19 (26)
<6/12	11 (18)	20 (28)
6/15	3 (5)	2 (3)
6/18	4 (7)	10 (14)
<6/18	4 (7)	1 (1)
Number plate chart*	4 (7)	1 (1)
Number plate outside†	3 (5)	9 (13)

*Indoor test with simulated number plate similarly mounted to Snellen chart and subtending same angle as number plate at 20.5 m.

†Includes all health professionals who would only offer this advice to patients or who would actively test patients in this way.

Questions to optometrists and ophthalmologists

When clients or patients ask you whether or not they can drive, providing that they have no diplopia or reduction in visual fields, at what level of acuity do you tell them that they should not drive, and how would you measure it?
Are there any other tests that you would do or information that you would seek?

What is already known on this topic

It is estimated that a Snellen acuity of 6/9⁻² produces the same failure rate as the number plate test at 20.5 m, leading to guidelines that a visual acuity between 6/9 and 6/12 is required for driving

What this study adds

A proportion of patients with binocular 6/9 vision failed to read a number plate at 20.5 m, and a major proportion with binocular 6/12 vision could read it

Snellen visual acuity is a poor indicator of an individual's chance of meeting the legal standard for driving, and all people with a visual acuity of 6/9 or less should be encouraged to self assess their vision

Patients receive a spectrum of advice from healthcare professionals about driving on the basis of a visual acuity of 6/9 or 6/12

distance outside the practice—this would provide a useful public service.

Conclusions

Snellen acuity is a poor indicator of an individual's chance of passing a number plate test, and it cannot be assumed that a driver with a visual acuity of 6/9 will

meet the standard for driving. All drivers with 6/9 vision or less must be encouraged to self assess. Conversely, it should not be assumed that a driver with a visual acuity of 6/12 is below the standard for driving, particularly as loss of the right to drive has such far reaching social implications.^{7,8} Advice that vision required for driving lies somewhere between 6/9 and 6/12 acuity could cause confusion if these points are not stressed.

Unjustified exclusion of elderly people from studies submitted to research ethics committee for approval: descriptive study

continued over

BMJ 2000;321:992-3

Ageism in clinical practice¹ and published research² is well recognised. We were interested in whether research protocols submitted to the local research ethics committee contained unjustified upper age limits and how the committee dealt with this.

Methods and results

We reviewed all studies submitted to Bro Taf local research ethics committee in the first seven months of 1999 to determine whether any upper age limits were justified and whether the committee had commented on such age restrictions. We then made a judgment on the appropriateness of the upper age limit.

Of 225 studies whose protocols were reviewed, 65 were on topics or conditions that automatically excluded elderly people. Five studies specifically concerned elderly people and had a lower age limit but no upper limit. Of the remaining 155, 90 (58%) had an upper age limit, which ranged from 45 years (in a smoking cessation intervention) to 100 years (in a

study of an open access mental health service), with a median of 70 years (interquartile range 65 to 75 years). In five studies an upper age limit was reasonable (participants were required to have no important disease, or prolonged follow up was planned).

In 85 studies the age restriction was inappropriate and unnecessary, but ethical review had failed to highlight this issue. Justification was offered by researchers in only one study. Age limits often conflicted with the aims of the study—for example, in a study of “subjects randomly selected to reflect each life stage,” another “of consecutive patients attending for bone scan,” and another that claimed “no special groups to be excluded.” In some studies exclusion of older patients was likely to result in an atypical clinical population—for example, an investigation of “exclusion of vulnerable people from services,” studies of type II diabetes, glaucoma, or non-steroidal anti-inflammatory drugs that were restricted to people aged under 65, and a study comparing incontinence aids that was limited to those aged under 70.
