Abstract

Objective To investigate the efficacy and tolerability of analgesic and adjuvant pain drugs typically administered in primary care for the management of patients with sciatica.

Design Systematic review.

Data source International Pharmaceutical Abstracts, PsycINFO, Medline, Embase, Cochrane Central Register of Clinical Trials (CENTRAL), CINAHL, and LILACS.

Study selection Randomised controlled trials assessing the efficacy and tolerability of drugs versus placebo or other treatment for sciatica.

Data extraction Two independent reviewers extracted data and assessed methodological quality using the PEDro scale. Pain and disability outcomes were converted to a common 0 to 100 scale. Data were pooled with a random effects model, and the GRADE approach was used in summary conclusions.

Results Twenty three published reports met the inclusion criteria. The evidence to judge the efficacy of non-steroidal anti-inflammatory drugs (NSAIDs), corticosteroids, antidepressants, anticonvulsants, muscle relaxants, and opioid analgesics ranged from moderate to low quality. Most of the pooled estimates did not favour the active treatment over placebo. The pooled results of two trials of corticosteroids (mean difference in overall and leg pain -12.2, 95% confidence interval -20.9 to -3.4) and a single trial of the anticonvulsant gabapentin for chronic sciatica (mean difference in overall pain relief -26.6, -38.3 to -14.9) showed some benefits but only in the short term. The median rate of adverse events was 17% (interquartile range 10-30%) for the active drugs and 11% (3-23%) for placebo. Trial limitations included failure to

use validated outcome measures, lack of long term follow-up, and small sample size.

Conclusions As the existing evidence from clinical trials is of low quality, the efficacy and tolerability of drugs commonly prescribed for the management of sciatica in primary care is unclear.

Introduction

The clinical syndrome of sciatica has been recognised since ancient times. Currently believed to arise from a disorder of the nerve root, the syndrome is known by a range of synonyms such as lumbosacral radicular syndrome, nerve root compromise, nerve root pain, and nerve root entrapment or irritation.^{1,2} Sciatica is considered to be a prognostic indicator of poor outcome among patients with low back pain^{3,4} with a substantial proportion continuing to have persistent pain for two years or longer.⁵ The annual prevalence of sciatica is estimated to be between 14%⁶ and 2%.⁷ While there are a range of definitions of sciatica,² the key clinical features that can help clinicians to distinguish it from non-specific low back pain include unilateral leg pain that is worse than the low back pain, pain radiating below the knee, presence of numbness or pins and needles in a dermatomal distribution, positive results on a straight leg raise test, and weakness or reflex changes, or both, in a myotomal distribution.¹

Analgesic and adjuvant pain drugs are often prescribed for patients with sciatica.⁸ Patients with a clinical diagnosis of sciatica are about five times more likely to take drugs than those with low back pain only.⁴ Drugs commonly prescribed for the

Appendix table B: Calculation of effect sizes for trials comparing different drugs

management of sciatica include non-steroidal anti-inflammatory drugs (NSAIDs), skeletal muscle relaxants, opioid analgesics, benzodiazepines, systemic corticosteroids, antidepressants, and anticonvulsants.⁹⁻¹⁰ While guidelines provide clear and generally consistent recommendations for the prescription of drugs for non-specific low back pain,¹¹⁻¹² this is not the case for sciatica.

At present the efficacy and tolerability of commonly prescribed analgesic and adjuvant drugs for the management of patients with sciatica has not been established. The problem is that there are no reviews that specifically focus on these drugs that are used in primary care to manage sciatica. Because most guidelines recommend a course of conservative care before surgery is considered, it is imperative to understand what best practice conservative care should entail. In this systematic review we determined the efficacy and tolerability of analgesic and adjuvant pain drugs typically administered in primary care (orally, topically, or parentally) in the management of patients with sciatica when compared with other treatment options or no treatment.

Methods

Data sources and searches

We used the review methods advocated by the editorial board of the Cochrane Back Review Group.¹³ This study searched the following databases from the earliest records to 15 March 2010: International Pharmaceutical Abstracts, PsycINFO, Medline, Embase, Cochrane Central Register of Clinical Trials, CINAHL, and LILACS. Key words related to randomised controlled trial, sciatica, and drugs terms in addition to subject subheadings and word truncations specific for each database were used (see appendix on bmj.com). Electronic searches were supplemented by hand searching reference lists of eligible clinical trials. Our search was restricted to trials published in English, German, Dutch, Portuguese, and Spanish. One reviewer screened all relevant titles and abstracts and excluded clearly irrelevant papers, leaving 173 potentially relevant papers. Two reviewers independently evaluated the full reports for eligibility. Disagreements were resolved by discussion.

Study selection

Studies were eligible if they were randomised controlled trials evaluating single or any combination of analgesic or adjuvant pain drugs. For the purposes of this review, we focused on pharmacological interventions that could be administered in primary care settings, which include drugs administered via oral, topical, or parental route (that is, intramuscular injection and intravenous bolus). We excluded trials evaluating procedures that require imaging assistance and the monitoring of anaesthesia monitoring capabilities (for example, epidural, extradural, and intradiscal injections) or that require an extended period of time to be administered with monitoring of the patient's vital signs (for example, intravenous infusion). Eligible comparisons included no treatment, placebo, or other treatment options (for example, other pharmacological treatment, surgery, epidural injections, or other conservative treatment).

To be eligible studies needed to explicitly report that participants had sciatica or a synonym for sciatica. Sciatica synonyms considered included radiculopathy, nerve root compromise, nerve root compression, lumbosacral radicular syndrome, nerve root pain, nerve root entrapment, and pain radiating below the knee. The intensity or duration of symptoms was not restricted, but participants were classified as having acute (less than six weeks), subacute (six to 12 weeks), or chronic (12 weeks or more) symptoms. Trials of mixed groups of patients with low

back pain were eligible if it was possible to clearly identify a subgroup with sciatica and data only from these participants were included in the analysis. There was no restriction related to the source of participants. Sciatica definitions across trials were classified as those based on clinical assessment alone and those that also require concordant imaging evidence.

Trial drugs were classified according to the Anatomical Therapeutic Chemical (ATC) classification system advocated by the World Health Organization's collaborating centre for drugs statistics methodology.¹⁴ Table 1 lists the classes of drugs and the ATC codes included in the search strategy of the original protocol.

Trials were included when one of the following outcome measures was reported: overall pain intensity (when not specified as leg or back pain), leg or back pain intensity, disability status, work status, and adverse events. We also included studies that did not report continuous data for these variables but reported percentage of improved patients. As the definition of improved (or not improved) was unclear or varied between studies, however, we did not pool these data. Work status, when identified, was listed as an outcome but pooling of these data was also not possible because of different definitions used across trials.

Data extraction and quality assessment

Two trained independent raters assessed the quality of the trials' methods using the PEDro scale.¹⁵⁻¹⁶ Disagreements were resolved by a third rater. Methodological quality was not an inclusion criterion.

Two independent reviewers extracted means (final scores or change score), standard deviations, and sample sizes from studies using a standardised data extraction form. When there was insufficient information in trial reports, we contacted authors or estimated data using methods recommended in the Cochrane Handbook for Systematic Reviews of Interventions.¹⁷ Briefly, when the mean was not reported we used the median; when standard deviations could not be estimated, we adopted the standard deviation from the most similar study.

To evaluate the overall quality of the evidence and the strength of the recommendation, we used the GRADE approach.¹⁸ We used an adapted version of the criteria advocated by the Cochrane Back Review Group.¹⁹ The quality of the evidence was downgraded by one level for each of four factors we encountered: limitations in the design (for instance, >25% of participants from studies with low quality methods—PEDro score <7 points); inconsistency of results (for instance, ≤75% of the participants report findings in the same direction); and imprecision (for instance, total number of participants <300 for each outcome). We did not assess publication bias with funnel plots as too few studies were included in the meta-analysis. We also did not assess indirectness as this review encompasses a specific population. Two reviewers judged whether these factors were present for each outcome. Single randomised studies (with under 300 participants) were considered inconsistent and imprecise (that is, sparse data) and provided "low quality evidence." This could be further downgraded to "very low quality evidence" if there were also limitations in design. We applied the following definitions of quality of the evidence²⁰:

- High quality—further research is unlikely to change our confidence in the estimate of effect. There are no known or suspected reporting biases; all domains fulfilled
- Moderate quality—further research is likely to have an important impact on our confidence in the estimate of effect

and might change the estimate; one of the domains was not fulfilled

- Low quality—further research is likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate; two of the domains were not fulfilled
- Very low quality—we are uncertain about the estimate; three of the domains were not fulfilled.

A GRADE profile was completed for each pooled estimate and for single trials comparing drugs versus placebo.

Data synthesis and analysis

Outcome data were extracted for immediate term (two or fewer weeks after randomisation), short term (more than two weeks but less than three months), intermediate term (more than three months but less than 12 months), and long term (12 months or more) follow-up evaluations. When multiple time points fell within the same category, we used the one closest to one week for the immediate term, eight weeks for the short term, six months for the intermediate term, and 12 months for the long term. Scores for pain intensity and disability were converted to a scale from 0 to 100. When more than one outcome measure was used to assess intensity of pain, disability, or work status, we included the outcome measure described as the primary outcome measure for the trial. Descriptive statistics were used to describe adverse events reported in each trial.

Trials that we considered clinically homogeneous were grouped according to class of drugs, comparison group, dose, outcomes (pain, disability, etc), and outcome assessment time points (immediate term, short term, intermediate term, and long term). Pooled estimates were obtained with Comprehensive Meta-Analysis software, version 2.2.04 (Biostat, Englewood, NJ). Pooled effects were calculated with a random effects model. For calculation of effect size (see appendix tables A and B on bmj.com), we pooled leg pain and overall pain, as leg pain is usually worse than pain in the back. When trials were not sufficiently homogeneous, pooling of data via meta-analysis was not performed and outcome measures of the individual studies were reported. We decided a priori that a sensitivity analysis would be conducted to investigate definitions of sciatica as possible sources of heterogeneity in effect size among included studies. The limited number of trials in the meta-analysis, however, prevented further investigation.

Results

Figure 1 outlines the flow of trials through the review. The initial electronic database search identified 2460 potential studies of interest. After screening citations by title and abstract, we considered 197 potentially eligible articles for inclusion and retrieved full articles. We included 23 published reports²¹⁻⁴³ (reporting 24 different clinical trials, as one²⁸ reported on two trials). Three trials reported in previous systematic reviews^{12 44-46} were not included in this review because of unclear randomisation.⁴⁷⁻⁴⁹

The included trials investigated six different classes of drugs: NSAIDs, antidepressants, corticosteroids, opioid analgesics, muscle relaxants, and anticonvulsants. The drugs investigated in the included trials were administered orally in 16 trials^{21-24 27 28 32 33 35-38 41-43} and parenterally in five trials (four trials^{25 30 39 40} investigated intramuscular injections and one trial²⁹ investigated intravenous infusions). Three other trials^{26 31 34} used mixed administration of a starting intramuscular dose and subsequent oral doses. One study compared oral versus

parenteral administration.²² Table 2 shows the characteristics of the included trials, and table 3 presents details of methodological quality.

Duration of symptoms varied a lot across studies (table 2). Six trials specifically investigated patients with chronic symptoms^{21 23 37 38 41 43} and eight trials included patients with acute symptoms.^{22 28-30 33 35 42} In six trials, however, patients had mixed duration of symptoms^{25 27 34 36 39 40}; in two trials duration was not specified^{26 32}; and in two trials patients were reported to have acute symptoms but no information regarding duration was provided.^{24 31} Regarding the definition of sciatica, 15 trials used a definition based on clinical assessment alone,^{21 23 24 26 28 30-35 39 40 42} whereas nine trials also required concordant imaging evidence.^{22 25 27 29 36-38 41 43} Pooling of data via meta-analysis was possible only for comparison of NSAIDs versus placebo in pain intensity at immediate follow-up and for corticosteroids versus placebo in pain intensity at immediate and short term follow-up. Table 2 also presents the number of studies comparing each class of drug and control.

Placebo controlled trials

Fifteen randomised clinical trials compared drugs with placebo with individual effect sizes calculated for nine trials (fig 2). For five trials investigating NSAIDs,³¹ corticosteroids,^{32 34} antidepressants,²¹ and muscle relaxants,²⁴ we did not calculate effect sizes as percentage of improved patients was reported as an outcome.

NSAIDs

Four trials compared orally administered NSAIDs with placebo for acute sciatica.^{28 33 42} Of these, three trials used a three arm design.^{28 33} Treatment effects for these studies are presented in figure 2. Data for pooling were available from all three studies. Figure 3 shows small and non-significant pooled effect size for pain (overall and leg pain) in the immediate term follow-up (mean difference -4.9, 95% confidence interval -10.2 to 0.4; $P<0.07$). Because of the three arm design, we calculated effect sizes for three other treatment comparisons (comparison 2 (meloxicam 7.5 mg/day, lornoxicam 8 mg/day, piroxicam 20 mg/day v placebo): mean difference -4.4, -8.9 to 0.1, $I^2=0.1\%$, $P<0.06$; comparison 3 (meloxicam 15 mg/day, lornoxicam 8 mg/day, piroxicam 2 mg/day v placebo): mean difference -3.9, -8.0 to 0.2, $I^2=0.6\%$, $P<0.07$; comparison 4 (meloxicam 15 mg/day, diclofenac 50-150 mg/day, piroxicam 20 mg/day v placebo): mean difference -4.4, -9.4 to 0.6, $I^2=6.8\%$, $P<0.09$) (not shown in fig 3). The quality of evidence (GRADE) for this pooling was rated “low quality” (downgraded for limitation of study design and inconsistency).

Corticosteroids

Three trials in patients with acute sciatica tested the effect of corticosteroids compared with placebo.^{29 30 35} The individual studies provided imprecise estimates of treatment effect (fig 2). For the immediate term, pooling showed no effect of steroids on leg pain (mean difference -1.8, -11.1 to 7.5; $P=0.71$) with a GRADE classification of “moderate quality” of evidence (downgraded for imprecision) (fig 3). For the short term, pooling showed a significant effect of steroids on pain (overall and leg pain) (mean difference -12.2, -20.9 to -3.4; $P<0.01$) and “moderate quality” of evidence according to the GRADE approach (downgraded for imprecision) (fig 3).

Antidepressants, anticonvulsants, and opioid analgesics

Three trials investigated the efficacy of antidepressants, anticonvulsants, and opioid analgesics (fig 2).^{37 38 43} As these were single trials that investigated different classes of drugs or time points of assessment, pooling was not possible. Hence, the quality of evidence for all these medications was considered “low quality” (single studies)^{37 43} or “very low quality” (single study downgraded for limitation of study design)³⁸ according to the GRADE approach.

Two trials investigated the effect of anticonvulsants in patients with chronic symptoms of sciatica. In one crossover trial,³⁸ topiramate (50–400 mg/day) showed no better immediate effects than placebo for disability and leg or back pain. In contrast, data from another trial⁴³ showed significant overall pain relieving effect with the anticonvulsant gabapentin (900–3600 mg) in the short term (mean difference –26.6, –38.3 to –14.9; $P < 0.001$) compared with placebo.

One crossover study with four periods investigated the relative efficacy of opioid analgesics (sustained release morphine 15 mg/day), antidepressants (nortriptyline 25 mg/day), and a combination of both and placebo in patients with chronic sciatica.³⁷ In this trial, antidepressants, opioid analgesics, and a combination of both had no significant effect compared with placebo in the immediate term for disability or leg or back pain.

NSAIDs v NSAIDs

Five studies compared one type of NSAID with other NSAIDs.^{25 28 33 39 40} Figure 4 shows all the comparisons involving different types of NSAIDs. None of these studies showed one NSAID to be better than the other. One study found no difference in overall pain between oral and parenteral administration of meloxicam 15 mg a day.²²

NSAIDs v other treatments

In three separate trials the NSAID diclofenac (50–75 mg/day) showed no difference in outcomes compared with antidepressant³⁶ or electroacupuncture⁴¹ but did worse than caudal epidural injections of corticosteroids²⁷ for pain and disability, specifically in the immediate follow-up (fig 3). In one trial the NSAID ketoprofen (200 mg/day) was no better than a combination of corticosteroids for pain in the immediate follow-up.²⁶

Adverse events

Adverse events were investigated in 75% (18/24) of the included trials (table 4); the median number of adverse events (interquartile range) was 17% (10–30%) for the active drugs and 11% (3–23%) for placebo. The rate and type of adverse events reported varied substantially between drugs and between trials for the same medicine.

Discussion

There is at best only low quality evidence to judge the efficacy and tolerability of drugs commonly prescribed for the management of sciatica in primary care. The available evidence does not clearly show favourable effects of NSAIDs, corticosteroids, antidepressants, or opioid analgesics in the immediate term, even compared with placebo. Evidence from a single trial and one meta-analysis with two trials provides some limited support (“low quality” and “moderate quality” evidence) for the use of NSAIDs and corticosteroids to relieve pain in the short term in patients with acute sciatica. In one

small sample trial there was also limited support (“low quality” evidence) for the short term relief of pain in chronic sciatica with an anticonvulsant drug. At present these data provide a lack of conclusive and high quality evidence to guide the prescription of these drugs for patients with sciatica in primary care.

Strengths and limitations of review

The strengths of this systematic review include the use of a prespecified protocol, inclusion of trials published in languages other than English, and the use of a highly sensitive search strategy to identify trials for sciatica coupled with search terms related to the nine classes of drugs of interest. We assessed methodological quality with the PEDro scale rather than the Cochrane Risk of Bias tool because the PEDro scale has been shown to have acceptable reliability¹⁶ and validity,^{15 50} whereas two studies have reported reliability limitations with the Cochrane tool.^{51 52} One limitation of our study is the possibility of publication bias as we did not attempt to identify unpublished trials that could be found in clinical trials registries and conference proceedings. Another limitation is that we could accommodate trials in only four languages other than English.

A strength of our review over past reviews is that we located 24 randomised clinical trials relevant to our question compared with six,¹² three,⁴⁶ and two^{44 45} trials included in the four previous reviews. Accordingly we provide more precise estimates of treatment effects, specifically for NSAIDs and corticosteroids, and a better description about tolerability of all classes of drug. Including more trials has allowed us to provide a more in-depth evaluation of the pharmacological treatments that have been tested for sciatica in primary care. For example, we have provided information on the efficacy of antidepressants and opioid analgesics whereas previous reviews did not cover these classes of drugs. Another strength of this review is that we quantitatively pooled trials where possible. This allowed us to explore the size of the treatment effect, which is not possible in a qualitative summary. In addition, we were able to assess the overall quality of the evidence with the GRADE approach. Although conclusions of previous reviews were based on a surprising paucity of evidence, our findings are likely to inform the direction of future research in this topic. In pharmacological trials for sciatica, we consider the priorities to include consideration of duration of symptoms, recruitment of large samples, and collection of outcomes relevant to patients. For instance, regarding duration of symptoms it would be reasonable to test corticosteroids and NSAIDs in trials in patients with acute sciatica, whereas given that chronic sciatica includes a neuropathic pain component, anticonvulsant and antidepressants might need to be tested in patients with a chronic condition.

Although the knowledge of evidence about surgery has changed in the past decade, we still do not know much about a simpler conservative treatment such as pharmacological interventions for sciatica. A recent clinical practice guideline from the American Pain Society⁵³ recommends that surgery should be considered as a treatment option for persistent and disabling radicular pain caused by a herniated lumbar disc. This recommendation relies on moderate short term benefits from large randomised clinical trials such as those by Peul et al^{54 55} and Weinstein et al,⁵⁶ with 283 and 501 patients randomised, respectively. At present, there is a limited number of mainly small trials of pharmacological interventions with typically short term follow-up. For example, the evidence to support the use of anticonvulsants in chronic sciatica arises from a single trial with only 50 participants.

Our principal finding is that there is insufficient evidence to confidently guide the use of any analgesic or adjuvant pain medicine for the effective management of pain and disability in patients with sciatica. Until this changes, we would advise clinicians treating such patients who exhibit clinical features of neuropathic pain to consider evidence based guidelines for neuropathic pain⁵⁷⁻⁵⁹ and for other patients with sciatica to consider therapeutic recommendations from current guidelines for the management of non-specific low back pain.¹¹

What is already known on this topic

Pain relieving drugs are often prescribed by general practitioners for patients with sciatica

While guidelines provide clear and generally consistent recommendations for the prescription of drugs for non-specific low back pain, this is not the case for sciatica

The efficacy and tolerability of drugs in the management of sciatica administered in primary care has not been established

What this study adds

There is low quality evidence for the efficacy of NSAIDs, corticosteroids, and anticonvulsants

The available evidence does not clearly show favourable effects of NSAIDs, corticosteroids, antidepressants, muscle relaxants, and opioid analgesics in the immediate term and provides limited support for the use of NSAIDs, corticosteroids, and anticonvulsants in the short term

At present these data provide a lack of conclusive and high quality evidence to endorse the prescription of these drugs for patients with sciatica in primary care

Tables

Table 1 | Classes of drugs and Anatomical Therapeutic Chemical (ATC) codes included in search strategy

	ATC code
Analgesics:	
Any	N02
Opioid analgesics	N02A
Paracetamol	N02BE01
Anticonvulsants (or antiepileptics)	N03
Antidepressants	N06A
Benzodiazepine derivatives	N05BA
Corticosteroids for systemic use	H02
Non-steroidal anti-inflammatory drugs	M01A
Skeletal muscle relaxants	M03

Table 2| Characteristics of included studies of pain relief in patients with sciatica

Study	Details of participants	Interventions (dose regimens and dosing duration)	Outcomes (measures) and time points
NSAID v placebo			
Grevsten 1975 ³¹	Source: outpatient department of surgical or surgical-orthopaedic clinic; n=36; group 1=18, group 2=18; age: 23-62; duration: acute (NS)	Group 1: IM phenylbutazone (0.6 g) on day 1, oral dose 0.2 g (two tablets) on days 2-4, oral dose 0.1 g (one tablet) in days 5-15 v group 2: IM distilled water, NaOH 1N to pH8 (0.6 g) on day 1, oral dose 0.2 g (two tablets) on days 2-4, oral dose 0.1 g (one tablet) on days 5-15. Additional analgesics allowed	% of improved patients; adverse events; at two weeks
Weber 1993 ⁴²	Source: patients recruited from practitioners and company doctors; n=208; group 1=120, group 2=94; age=48 (SD NS); duration: acute (onset of pain within 14 days)	Group 1: 20 mg oral piroxicam v group 2: oral placebo. Twice daily for first two days, followed by once daily for next 12 days. Additional analgesics allowed	Leg and back pain (0-100 scale); disability (RM); adverse events; work status (no/sometimes/often); at 1, 2, 3, and 4 weeks
Dreisser 2001 ²⁸ :			
Placebo control study	Source: 79 centres in 6 countries; n=532; group 1=117 (mean (SD) age 47 (14)), group 2=181 (47 (15)), group 3=180 (47 (14)); duration: acute (onset of pain within 3 days)	Group 1: 7.5 mg oral meloxicam v group 2: 15 mg oral meloxicam v group 3: oral placebo. Once daily for 7 days	Overall pain (0-100 scale); adverse events; day 3 and day 7
Diclofenac control study	Source: 117 centres in 10 countries; n=489; group 1=164 (mean (SD) age 46 (14)), group 2=163 (45 (14)), group 3=162 (44 (13)); duration: acute (onset of pain within 3 days)	Group 1: 7.5 mg oral meloxicam once daily v group 2: 15 mg oral meloxicam once daily v group 3: 50 mg oral diclofenac three times daily for 14 days. Additional analgesics allowed in both studies	
Herrmann 2009 ³³	Source: outpatients from general practices; n=171; group 1=57 (mean (SD) age 52 (15)), group 2= 57 (49 (14)), group 3=57 (48 (12)); duration: acute (onset of pain within 3 days)	Group 1: 8 mg oral lornoxicam x2 on day 1 (loading dose)+1 capsule after 8 hours, twice daily on day 2-4, once on day 5; v group 2: 50 mg oral diclofenac one/day on day 1, 3 times/day on days 2-4, once on day 5 (optional) v group 3: oral placebo (capsules added to group 1 and group 2 blister packs)	Overall pain (0-100 scale), adverse events, at 3, 4, 6, and 8 hours
Corticosteroids v placebo			
Hofferberth 1982 ³⁴	Source: NS; n=91; group 1=38, group 2=53; age: 47 (range 30-70); duration: mixed (>1 month)	Group 1: IM dexamethasone (168 mg) v group 2: IM placebo; 2 ampoules 3 times/day on day 1-5, one ampoule 3 times/day on days 6-8, one ampoule twice on day 9, one ampoule on day 10. Additional analgesics and physiotherapy were allowed	% of improved patients at 11 days, 6 weeks, and 6 months
Haimovic 1986 ³²	Source: NS; n=33; group 1=21, group 2=12; age: NS; duration: NS	Group 1: oral dexamethasone v group 2: oral placebo; 64 mg on day 1, 32 mg on day 2, 16 mg on day 3, 12 mg on day 4, 8 mg on days 5-7. Additional analgesics allowed and participants kept on bed rest for 7 days of treatment	% of improved patients at 7 days and 12 months
Finckh 2006 ²⁹	Source: university and non-university hospitals; n=60; group 1=31 (mean (SD) age 49 (18)), group 2=29 (45 (13)); duration: acute (>1 week to <6 weeks)	Group 1: single IV infusion bolus of 500 mg methylprednisolone v group 2: single intravenous infusion of 0.9% saline; additional analgesics, NSAIDs, glucocorticoids, and physical therapy allowed	Leg pain (0-100 scale), adverse events, on days 1-3 and day 10
Holve 2008 ³⁵	Source: primary care or emergency departments; n=29; group 1=15 (age 39 (95% CI 33 to 46)), group 2=14 (43 (38 to 46)); duration: acute (onset of pain within 1 week)	Group 1: oral prednisolone (60 mg/day for three days, 40 mg/day for 3 days, and 20 mg/day for 3 days) v group 2: oral placebo (containing inert filler substance); daily oral administration 60 mg on days 1-3, 40 mg on days 4-9, 20 mg on days 7-9. Additional analgesics allowed and, if needed; activity as tolerated; and referral to physical therapy	Pain (0-5 scale), disability (ODI), adverse events, work status (No of hours patients was employed), at 1, 2, 3, and 4 weeks, and 2, 3, 4, 5, and 6 months
Friedman 2008 ³⁰	Source: teaching hospital; n=82; group 1=39 (mean (SD) age 39 (9)), group 2=43 (37 (8)); duration: acute (≤7 days)	Group 1: IM methylprednisolone (160 mg) v group 2: IM placebo. Additional analgesics, opioid analgesics, and NSAIDs allowed	Overall pain (0-10 scale), adverse events. Work status (rate of return to work), at 1 month
Antidepressant v placebo			
Atkinson 1998 ²¹	Source: university medical primary care centre, orthopaedic clinic, and local community; n=15; group 1=6 (mean (SD) age 46 (11)), group 2=9 (47 (11)); duration: chronic (≥6 months)	Group 1: oral nortriptyline v group 2: oral doses of placebo. Both groups received identical capsules: 25 mg/day for 3 days; 50 mg/day for 4 days, 75 mg for 3 days, and 100 mg/day for 4 days. Additional analgesics allowed	% of improved patients at 8 weeks
Anticonvulsant v placebo			
Yildirim 2003 ⁴³	Source: outpatient setting; n=50; group 1=25 (mean (SD) age 38 (7)), group 2=25 (41 (11)); duration: chronic (group 1= 69.3 (3-180) months, group 2= 67.7 (5-240) months)	Group 1: oral gabapentin 900-3600 mg divided in 3 doses on day 1 depending on tolerability v group 2: oral placebo 3/day for 8 weeks	Overall pain (0-3 scale), adverse events, at 1 and 2 months

Table 2 (continued)

Study	Details of participants	Interventions (dose regimens and dosing duration)	Outcomes (measures) and time points
Khoromi 2005 ³⁸ (cross over)	Source: recruited through local newspaper advertisements; n=29; age: 53 (28-74); duration: chronic (>3 months)	Group 1: oral topiramate 50 mg in 2 divided doses in week 1, 50 mg increments in each morning and night doses to maximum of 400 mg in weeks 2-4 v group 2: oral doses of diphenhydramine (placebo) 6.25 mg twice/day in week 1, increased by 6.25 mg increments in each dose in week 2, increased by 12.5 mg increments in each dose in week 3 to maximum of 50 mg/day in 2 divided doses. Each period consisted of 4 weeks of drug titration and 2 weeks of maintenance, followed by 2 week washout, during which doses were tapered	Leg pain (0-10 scale), adverse events at 8 weeks
Baron 2010 ²³	Source: 46 centres in 8 countries; n=217; group 1=110 (mean (SD) age 53 (11)), group 2=107 (53 (13)); duration: chronic (>3 months)	Group 1: oral pregabalin, 5 weeks at optimal dose established in single blind phase) v group 2: oral placebo (pregabalin dose tapered off during first 7 days, then placebo administered for 4 weeks). Trial started after 1 week single blind run-in phase to identify and exclude placebo responders, followed by 4 week single blind pregabalin treatment phase with flexible dose pregabalin 150-600 mg/day to identify responders. Additional analgesics allowed	% of improved patients, adverse events on day 7, 14, 21, 28, and 35
Muscle relaxants v placebo			
Berry and Hutchinson, 1988 ²⁴	Source: outpatients from general practices; n=117; group 1=28 (mean (SD) age 44 (13)), group 2=31(38 (13)); duration: acute (NS)	Group 1: 4 mg oral tizanidine 3 times/day for 7 days v group 2: oral placebo (3 times/day for 7 days). Additional analgesics allowed	% of improved patients on day 3 and 7
NSAID v NSAID*			
Borms 1988 ²⁵	Source: NS; n=40; group 1=20 (mean (SD) age 37 (10)), group 2=20 (42 (15)); duration: mixed (<6 months)	Group 1: twice daily 200 mg IM tiaprofenic twice/day for 4 days v group 2: 100 mg IM ketoprofen twice/day for 4 days	Overall pain (0-100 scale), adverse events on days 1, 2, 3, and 4
Scheurmans 1988 ⁴⁰	Source: NS; n=26; group 1=14 (mean (SD) 50 (9)), group 2=12 (49 (13)); duration: mixed (<6 months)	Group 1: 200 mg IM tiaprofenic twice/day for 4 days v group 2: 656 mg IM alclofenac twice/day for 4 days	Overall pain (0-100 scale), adverse events on days 1, 2, 3, and 4
Rachid 1992 ³⁹	Source: NS; n= 60; group 1=30 (mean (range) age 51 (29-68)), group 2=30 (53 (26-60)); duration: mixed (<12 weeks)	Group 1: 100 mg/day IM intramuscular injections of ketoprofen twice/day for 7 days v group 2: 75 mg/day IM diclofenac twice/day for 7 days	Overall pain (0-100 scale), adverse events on days 1, 2, 3, 4, 5, 6, and 7
Auvinet 1995 ²²	Source: 22 centres in three countries; n=113; group 1=54 (mean (SD) age 47 (10)), group 2=59 (42 (11)); duration: acute (<35 days)	Group 1: IM meloxicam (15 mg in 1.5 ml aqueous solution) and oral placebo (1 capsule) v group 2: 15 mg oral meloxicam capsule and one 1.5 ml IM placebo injection. Patients kept on strict bed rest during 24 hour study	Overall pain (0-100 scale), adverse events at 15, 30, 45, 60, 75, and 90 min and 2, 3, 4, 6, 9, 24 hours
NSAID v corticosteroids combination			
Braun 1982 ²⁶	Source: NS; n= 37; group 1=17, group 2=20); age: NS; duration: NS	Group 1: 2x200 mg/day IM ketoprofen on days 1-3, (200 mg/day), 4x50 mg oral+1x100 mg suppository ketoprofen on days 4-8 v group 2: 1st-3rd day 1 IM combination (phenylbutazone, carbamoyl-phenoxyacetic acid, dexamethasone, lidocaine (lignocaine) hydrochloride, cyanocobalamin) on days 1-3, 3 oral capsules+1 suppository on days 4-8. Additional analgesics allowed	Overall pain (0-100 scale) on day 4 and 9
NSAID v caudal epidural injection			
Dincer 2007 ²⁷	Source: NS; n= 64; group 1=30 (mean (SD) age 29 (6)), group 2=34 (28 (6)); duration: mixed (>1 month to <12 months)	Group 1: 75 mg oral diclofenac twice/day for 14 days v group 2: single injection (40 mg methylprednisolone acetate, 8 mg dexamethasone phosphate, 7 ml 2% prolocaine HCl, 10 ml 0.9% NaCl). Both groups instructed to perform lumbopelvic mobilisation and lumbar stabilisation exercise on daily basis. Additional analgesics allowed after day 14	Overall pain (0-10 scale), disability (ODI) on day 15 and at 1 and 3 months
NSAID v acupuncture			
Wang 2004 ⁴¹	Source: outpatients from acupuncture centre; n=40; group 1=23, group 2=17; age: NS; duration: chronic (>2 years)	Group 1: 25 mg oral diclofenac twice/day for 5 days v group 2: 25 minute electroacupuncture/day for 7 days	Leg pain (0-10 scale) on day 7
NSAID v antidepressant			
Kanayama 2005 ³⁶	Source: hospital (orthopaedic department); n=40; group 1=20 (mean (SD) age 34 (17)), group 2=20 32 (9)); duration: mixed (<1 to >3 months)	Group 1: 75 mg oral diclofenac v group 2: 300 mg oral 5-HT inhibitor for 2 weeks	Leg and back pain (0-100 scale) at 2 weeks
Opioid analgesic v antidepressant v placebo			

Table 2 (continued)

Study	Details of participants	Interventions (dose regimens and dosing duration)	Outcomes (measures) and time points
Khoromi 2007 ³⁷ (crossover study)	Source: recruited through local newspaper advertisements; n=28; age: 53 (range 19-65); duration: chronic (≥3 months)	Group 1: 15 mg oral sustained release morphine v group 2: 25 mg oral nortriptyline v group 3: 15 mg oral morphine+25 mg nortriptyline v group 4: oral inert placebo (0.25 mg benztropine, mimics side effects of other). All drugs tapered over 10 day period and patients drug-free for another 4 days before starting next period. Doses above are starting doses, subsequent doses depended on tolerability	Leg and back pain (0-10), disability (ODI), adverse events, day 10

IM=intramuscular; NS=not specified; IV=intravenous. ODI=Oswestry disability index. NSAID=non-steroidal anti-inflammatory drug. RM=Roland Morris disability questionnaire.

*Dreiser²⁸ and Herman³³ could be included in this comparison as both studies included comparisons of NSAID v NSAID.

Holve 2008 ³⁵	Prednisolone 20-60 mg (0)	Placebo (0)	NS	NS	—
Friedman 2008 ³⁰	Methylprednisolone 160 mg (11/39; 28%)	Placebo (8/43; 19%)	NS	NS	Drowsiness (11); stomach pain (6); mood changes (1); bloating (1)
Yildirim 2003 ⁴³	Gabapentin 900-3600 mg (2/25; 8%)	Placebo (0)	NS	NS	Dizziness (1); somnolence (1); chest pain (1); fainting (1)
Khoromi 2005 ^{38*} †	Topiramate 50-400 mg (24/28; 86%)	Placebo (20/28; 72%)	NS	NS	Paraesthesia (17); fatigue/weakness (19); sedation (11); diarrhoea (11); headache (6); constipation (2); depression (2); joint pain (3); leg cramps (7); amnesia (1); anorexia (1); frequent urination (1); thirst (1); eyes twitching (1); oedema (1); speech difficulty (1); blurred vision (1); photophobia (1); bleedings gums (1); tremor (1); somnolence (1); extremely yellow urine (1); decreased libido (1)
Baron 2010 ^{23‡}	Pregabalin 150-600 mg (31/110; 28%)	Placebo (26/107; 24%)	NS	NS	Dizziness (6); somnolence (2); fatigue (2); dry mouth (2); constipation (1); headache (5); weight increase (5); peripheral oedema (7).
Borms 1988 ²⁵	Tiaprofenic 400 mg (6/20; 30%)	Ketoprofen 200 mg (9/20; 45%)	NS	NS	Stomach pain (7); allergic skin reaction (3); pain on injection (3); dizziness (1); headache (1)
Scheurmans 1988 ⁴⁰	Tiaprofenic 400 mg (2/14; 14%)	Alclofenac 1312 mg (4/12; 33%)	NS	NS	Pruritus (1); pain on injection (1); allergic skin reaction (2); gastralgia (2); vertigo (1)
Rachid 1992 ³⁹	Ketoprofen 200 mg (11/30; 37%)	Diclofenac 150 mg (10/30; 33%)	NS	NS	Epigastric pain (9); nausea (11), pyrosis (6).
Auvinet 1995 ²²	IM meloxicam 15 mg (5/52; 9%)	Oral meloxicam 15mg (6/59; 10%)	NS	NS	Erythematous rash (1); dizziness (1); headache (3); dry mouth (2); palpitations (1); neutropenia (1); leucopenia (1); nocturia (1)
Braun 1982 ²⁶	Ketoprofen 200 mg (0)	Combination preparation (0)	NS	NS	—
Khoromi 2007 ^{37*}	Nortriptyline 25 mg (19/28; 68%)	Morphine 15 mg (26/28; 93%)	Combination (25/28; 89%)	Placebo (14/28; 50%)	Constipation (47); dry mouth (30); headache (14); drowsiness (13); tired/fatigue (19); dizziness (8); insomnia (8); nausea (3); difficulty urinating (4); sexual dysfunction (4); abdominal pain (4); weakness (2); decreased appetite (3); heartburn (4); blurred vision (6); thirsty/dehydrated (2); weight gain (2)

NA=not stated; IM=intramuscular.

*Crossover study and adverse effects only for completers.

†Nine patients dropped out from study because of adverse effects of topiramate: acral paraesthesia (2); nausea and anorexia (2); sedation and amnesia (3); depression and anxiety (1); rash (1).

‡Only most common adverse events listed.

Figures

Fig 1 Selection process of trials examining pain relief in patients with sciatica

Fig 2 Mean difference for pain and disability in placebo controlled trials on pain relief in patients with sciatica. Overall pain, leg pain, back pain, and disability expressed on common 0-100 scale. Immediate=follow-up evaluations ≤ 2 weeks after randomisation; short term=follow-up evaluations >2 weeks but ≤ 3 months; intermediate=follow-up evaluations >3 months but <12 months; long term= ≥ 12 months. NSAID=non-steroidal anti-inflammatory drug

Fig 3 Pooled mean difference for immediate pain in trials comparing NSAID v placebo. Pain expressed on common 0-100 scale. Immediate=follow-up evaluations ≤ 2 weeks after randomisation; short term=follow-up evaluations > 2 weeks but ≤ 3 months; intermediate=follow-up evaluations > 3 months but < 12 months; long term= ≥ 12 months. NSAID=non-steroidal anti-inflammatory drug

Fig 4 Mean difference for pain and disability in trials comparing NSAID versus NSAID or other treatments. Overall pain, leg pain, back pain and disability expressed on common 0-100 scale. Immediate=follow-up evaluations ≤ 2 weeks after randomisation; short term=follow-up evaluations > 2 weeks but ≤ 3 months; intermediate=follow-up evaluations > 3 months but < 12 months; long term= ≥ 12 months. NSAID=non-steroidal anti-inflammatory drug. *Injection contains methylprednisolone 40 mg, dexamethasone 8 mg, 2% procaine 7 ml, 0.9% NaCl 10 ml)
