Covid-19: Fact check—how many patients in hospital are unvaccinated?

Bryan Christie

Intensive care units in the UK are filling up with patients with covid-19 who have not been fully vaccinated, a number of media reports have claimed over the past week.

It led to the prime minister, Boris Johnson, urging people to get vaccinated to reduce the pressure on hospitals. He said that he had been told by doctors that as many as 90% of patients with covid-19 in intensive care had not received a booster vaccination.¹ Other media reports have suggested that 80-90% of patients in intensive care are unvaccinated.²

Are these reports accurate?

The Intensive Care National Audit and Research Centre (ICNARC), which has been monitoring activity throughout the pandemic, provides information on admissions to intensive care.³ Its latest report, published on 31 December, showed that the proportion of patients admitted to critical care in December 2021 with confirmed covid-19 who were unvaccinated was 61%. This proportion had previously fallen from 75% in May 2021 to 47% in October 2021—consistent with the decreasing proportion of the general population who were unvaccinated—before rising again in December 2021.

The proportion of unvaccinated patients in intensive care varied by English region, with the highest rates recorded in London (66%), the south west, and the north west. Being unvaccinated was classed as a person having no record of receiving any vaccination or having had a first dose administered within 14 days of receiving a positive covid test, and only 1.9% of the “unvaccinated” group had received a first dose within that period.

The 61% figure is lower than the 80-90% reported at some hospitals. But the latest ICNARC data span only to 15 December, and the proportion of patients in intensive care who are unvaccinated may have increased as the omicron variant spread in December. Some hospitals will also have been more badly affected than others.

What about admissions outside intensive care?

The UK Health Security Agency (UKHSA) has recently started to report hospital admissions—not just those to intensive care—alongside vaccination status. The latest figures show that in the week to 29 December 2021 a total of 815 people with confirmed omicron infection were admitted from an emergency department to hospitals in England. Of these, 74% had not had three doses of vaccine—including 25% (206) who were unvaccinated, 6% (49) who had received one dose, and 43% (352) who had received

two doses. Twenty three percent (189) had received a booster dose, and the remainder were unknown or had had their first dose less than three weeks ago.⁴

Further analysis by the agency has concluded that unvaccinated adults are as much as eight times more likely to be admitted to hospital than those who have been vaccinated and that booster doses are 88% effective at preventing hospital admission.⁴

A separate report published by the UKHSA showed that, although unvaccinated individuals made up only a small proportion of the overall population, they accounted for 27% of those with a confirmed case of omicron admitted to hospital in England and for 39% in London.⁵

The Office for National Statistics' latest report on deaths from covid-19 covering the period from January to October last year in England found that the age adjusted rate of death was 96% lower in people who had received a second dose of vaccine than in those who were unvaccinated.⁶

Do we need better data in the UK?

The UK has a wealth of data on the positive impact of vaccination, but the figures are held in different places and piecing them together is not simple. This has led to calls for the UK to follow the lead of the US Centers for Disease Control and Prevention, which publishes daily information on the progress of the pandemic, including infection rates by vaccination status.⁷
