Abstract

Objectives To evaluate the haematological findings of patients with severe acute respiratory syndrome (SARS).

Design Analysis of the demographic, clinical, and laboratory characteristics of patients with SARS.

Setting Prince of Wales Hospital, Hong Kong.

Subjects All patients with a diagnosis of SARS between 11 March and 29 March 2003 who had no pre-existing haematological disorders.

Main outcome measures Clinical end points included the need for intensive care and death. Univariate and multivariate analyses were performed to examine factors associated with adverse outcome.

Results 64 male and 93 female patients were included in this study. The most common findings included lymphopenia in 153 (98%) of the 157 patients, neutrophilia in 129 (82%), thrombocytopenia in 87 patients (55%), followed by thrombocytopenia in 77 (49%), and isolated prolonged activated partial thromboplastin time in 96 patients (63%). The haemoglobin count dropped by more than 20 g/l in 95 (61%) patients. Four patients (55%), followed by thrombocytosis in 77 (49%), neutrophilia in 129 (82%), thrombocytopenia in 87 patients (55%), and lymphopenia in 153 (98%) of the 157 patients. Four patients (55%) developed disseminated intravascular coagulation. Lymphopenia was shown in haemato-lymphoid organs at postmortem examination. Multivariate analysis showed that advanced age and a high concentration of lactate dehydrogenase at presentation were independent predictors of an adverse outcome. Subsets of peripheral blood lymphocytes were analysed in 31 patients. The counts of CD4 positive and CD8 positive T cells fell early in the course of illness. Low counts of CD4 and CD8 cells at presentation were associated with adverse outcomes.

Conclusions Abnormal haematological variables were common among patients with SARS. Lymphopenia and the depletion of T lymphocyte subsets may be associated with disease activity.

Introduction

An outbreak of severe acute respiratory syndrome (SARS) has recently been reported from Hong Kong. A novel coronavirus has been identified as the aetiological agent of the syndrome. Viral infection may produce various haematological changes. Early studies have shown that lymphopenia and thrombocytopenia are common among patients with SARS. This study summarises the haematological findings in patients with SARS who were treated at the Prince of Wales Hospital, Hong Kong.
Methods

Study population

Our study included all consecutive patients who received a diagnosis of SARS and were treated at the Prince of Wales Hospital but excluded patients with a history of haematological disorders. Based on the criteria for SARS that have been established by the US Centers for Disease Control and Prevention (CDC), our case definition was a fever (temperature >38°C), a chest radiograph or a computed tomographic image of the thorax showing evidence of consolidation with or without respiratory symptoms, and a history of close contact with a person in whom SARS had been diagnosed. The diagnosis was confirmed by an indirect immunofluorescence assay with fetal rhesus kidney cells that were infected with coronavirus and fixed in acetone to detect a serological response to the virus or by a positive viral culture.

Laboratory studies

Initial haematological investigations included a complete blood count with differential count and clotting profile (prothrombin time, activated partial thromboplastin time, and international normalised ratio). We studied these variables daily until a patient's fever had subsided for three days, then as clinically indicated, and at follow up visits after discharge from hospital. In some patients the chosen method was immunophenotyping with MultiTEST IMK kit, using flow cytometry (FACSCalibur 4 color system, BD Biosciences, California). We conducted postmortem investigations in some patients who died of SARS.

Data collection and analysis

We analysed the reported demographic, clinical, and laboratory characteristics. Day 1 was defined as the day of onset of fever. The clinical composite end point was the need for care in an intensive care unit, death, or subsidence for three days, then as clinically indicated, and the day 1 was defined as the day of onset of fever. The clinical composite end point was the need for care in an intensive care unit, death, or subsidence for three days, then as clinically indicated, and the day 1 was defined as the day of onset of fever. The clinical composite end point was the need for care in an intensive care unit, death, or subsidence for three days, then as clinically indicated, and the day 1 was defined as the day of onset of fever. The clinical composite end point was the need for care in an intensive care unit, death, or subsidence for three days, then as clinically indicated, and the day 1 was defined as the day of onset of fever.

Results

Between 11 and 29 March 2003 SARS was diagnosed in 160 patients at the Prince of Wales Hospital. We excluded three patients with a history of pancytopenia due to myelodysplastic syndrome (n=2) and systemic lupus erythematosus (n=1) from our analysis. We documented seroconversion or a greater than fourfold increase in antibody titre between acute and convalescent sera in 138 patients. Serum samples were not available in the remaining 19 convalescing patients, but six of them tested positive for coronavirus on culture. The study included 64 male and 93 female patients, all ethnic Chinese. Their mean age was 58.5 years (range 20-83 years). The median duration of follow up was 26 days (range 4-38 days). All patients received broad spectrum antibiotics and a combination of ribavirin and prednisolone 0.5 mg/kg/day as empirical treatment. Intravenous methylprednisolone at high dosage was used in patients with respiratory distress or progressive consolidations on their chest radiograph.

White blood cells

Transient leucopenia (leucocyte count <4×10^9/l) was found in 100 (64%) of patients during their first week of illness. Ninety six patients (61%) developed leucocytosis (leucocyte count >11×10^9/l), mostly during the second and third week of illness.

Neutrophils

Four patients (2.5%) developed transient neutropenia (absolute neutrophil count <0.5×10^9/l) lasting for one to two days. We noted neutrophilia (absolute neutrophil count >7.5×10^9/l) in 129 (82%) of patients. Univariate analysis showed that neutrophilia at any time was associated with a higher incidence of bacterial infections, documented by microbiological cultures (P=0.017). Most of these infections were hospital acquired pneumonia or line sepsis.

Lymphocytes

Lymphopenia (absolute lymphocyte count <1000/mm^3) was noted in 153 (98%) of patients during their course of illness. Most patients had a normal lymphocyte count at the onset of disease. Progressive lymphopenia occurred early in the course of illness and reached its lowest point in the second week in most cases. The lymphocyte count commonly recovered in the third week, but about 30% (14 of 47) of patients remained lymphopenic at the fifth week of SARS (fig 1).

We analysed subsets of peripheral blood lymphocytes in 31 patients. The mean CD4 and CD8 cell counts at presentation were 280.7 (SD 142.2) cells/μl (normal range 410 to 1590 cells/μl) and 242.2 (SD 130.8) cells/μl (normal range 62 to 559 cells/μl) respectively. Most patients had reduced CD4 and CD8 counts at presentation were 286.7 (SD 142.2) cells/l, mostly during the second and third week of illness. We noted neutrophilia (absolute neutrophil count >7.5×10^9/l) in 129 (82%) of patients. Univariate analysis showed that neutrophilia at any time was associated with a higher incidence of bacterial infections, documented by microbiological cultures (P=0.017). Most of these infections were hospital acquired pneumonia or line sepsis.

Lymphopenia (absolute lymphocyte count <1000/mm^3) was noted in 153 (98%) of patients during their course of illness. Most patients had a normal lymphocyte count at the onset of disease. Progressive lymphopenia occurred early in the course of illness and reached its lowest point in the second week in most cases. The lymphocyte count commonly recovered in the third week, but about 30% (14 of 47) of patients remained lymphopenic at the fifth week of SARS (fig 1).

We analysed subsets of peripheral blood lymphocytes in 31 patients. Most patients had reduced CD4 and CD8 counts at presentation were 286.7 (SD 142.2) cells/l, mostly during the second and third week of illness. We noted neutrophilia (absolute neutrophil count >7.5×10^9/l) in 129 (82%) of patients. Univariate analysis showed that neutrophilia at any time was associated with a higher incidence of bacterial infections, documented by microbiological cultures (P=0.017). Most of these infections were hospital acquired pneumonia or line sepsis.

Lymphopenia (absolute lymphocyte count <1000/mm^3) was noted in 153 (98%) of patients during their course of illness. Most patients had a normal lymphocyte count at the onset of disease. Progressive lymphopenia occurred early in the course of illness and reached its lowest point in the second week in most cases. The lymphocyte count commonly recovered in the third week, but about 30% (14 of 47) of patients remained lymphopenic at the fifth week of SARS (fig 1).

We analysed subsets of peripheral blood lymphocytes in 31 patients. The mean CD4 and CD8 cell counts at presentation were 280.7 (SD 142.2) cells/μl (normal range 410 to 1590 cells/μl) and 242.2 (SD 130.8) cells/μl (normal range 62 to 559 cells/μl) respectively. Most patients had reduced CD4 and CD8
patients (61%) and by more than 30 g/l in 44 patients (28%). We found no evidence of major bleeding, and no patient needed a transfusion or withdrawal of ribavirin. Of the 95 patients with a haemoglobin drop of more than 20 g/l, 57 showed evidence of haemolysis (rise of bilirubin >20 µmol/l or reticulocyte count >1%, or both). We found no evidence of an immune related cause of haemolysis. Haemoglobin concentrations recovered gradually after treatment with ribavirin was stopped in all patients.

**Clotting profile**

We excluded from the analysis four patients with mechanical heart valve prostheses (n=3) and atrial fibrillation (n=1) who were taking long term warfarin. Of the remaining 155 patients, 96 (63%) had isolated prolonged activated partial thromboplastin time (>40 seconds) and normal prothrombin time during their course of illness (fig 4). The prolonged activated partial thromboplastin time ranged from 40.1 seconds to 68.1 seconds and occurred mainly in the first two weeks of illness. We found no evidence of venous thromboembolism or other coagulation abnormalities such as the presence of the anticardiolipin antibody or raised fibrinogen concentrations. No patient required plasma transfusion or treatment with clotting factors. The abnormal clotting profile was self limiting, and all patients showed a normal activated partial thrombo-

---

**Platelet count**

Eighty seven patients (55%) developed thrombocytopenia (platelet count <140 000/mm³) during the course of their illness. Most of them had mild thrombocytopenia, and only three (2%) patients had a platelet count below 50 000/mm³ (fig 1). Most patients' platelet count was normal at the onset of illness. Progressive thrombocytopenia occurred and reached a low point at the end of the first week. Thrombocytopenia was self limiting and resolved by the fourth week of illness. No patient had major bleeding or required platelet transfusion.

Reactive thrombocytosis (platelet count ≥400 000/mm³) was noted in 77 (49%) of patients (fig 3). The platelet count peaked on a median of day 17 of illness (range day 6 to 31). Only one patient had a platelet count above 1 000 000/mm³, and she had no evidence of thromboembolism.

**Haemoglobin**

Except for four patients with haemoglobin counts ranging from 95 g/l to 105 g/l due to β thalassaemia trait (n=1), iron deficiency (n=2), and alcoholic liver disease (n=1), all patients had normal haemoglobin counts at presentation. After two weeks of taking ribavirin at a dosage of 400 mg every 8 hours intravenously or 1200 mg thrice daily orally, the haemoglobin count dropped by more than 20 g/l from baseline in 95

**Fig 4** Proportion of patients with abnormal activated partial thromboplastin time during the course of SARS. The number in parentheses indicates the number of observations available at each of the different time points
plasmin time at week 4. Fifty two patients (54%) had normal clotting profiles throughout the course of their illness.

Four patients (2.5%) developed frank disseminated intravascular coagulation with markedly prolonged prothrombin time, activated partial thromboplastin time, thrombocytopenia, and raised a2-microglobulin concentrations. One patient had respiratory failure and needed mechanical ventilation at the time of analysis. The other three patients died of severe respiratory distress with multiorgan failure, and two of them had superimposed bacterial infections.

Factors associated with admission to intensive care and death
Univariate analysis showed that the development of thrombocytopenia and high absolute neutrophil count at presentation were associated with admission to intensive or death (table). In the multivariate analysis, advanced age and a high concentration of lactate dehydrogenase at presentation were independent predictors of adverse outcomes. In the subgroup of patients whose lymphocyte subsets were analysed, low CD4 and CD8 counts at presentation were associated with adverse outcomes.

Haematolymphoid pathology
At autopsy the haematolymphoid organs of the four patients who died showed no enlarged lymph nodes in peripheral soft tissues or other body parts. We noted no reactive lymphoid hyperplasia or T zone reaction. The splenic white pulps of all cases appeared atrophic with lymphoid depletion, and the red pulp was congested (fig 5). Bone marrow appeared active with presence of three lineages. We noted no features of hypoplastic marrow or reactive haemophagocytic syndrome in any of the patients. The pulmonary pathology was dominated by diffuse alveolar damage, and the lymphoid infiltrate was sparse. Viral isolation, in particular for coronavirus, showed negative results in the splenic, lymph node, and bone marrow tissues.

Discussion
Abnormal haematological variables were common among patients with the new respiratory illness known as SARS, which has had a large impact worldwide. Lymphopenia and the depletion of T lymphocyte subsets may be associated with disease activity. Studies of its effect on various body systems are crucial to the understanding of this disease. Lymphopenia was the most common finding in our study in a cohort of 157 patients with SARS. Postmortem findings showed lymphopenia in various lymphoid organs. We found no features of bone marrow failure or reactive haemophagocytic syndrome. The inflammatory exudates in the lungs showed scanty lymphocytes. In those patients whose lymphocyte subset was analysed, both mean CD4 and CD8 cell counts were low at presentation and fell further during the early course of illness. The patients in this subgroup were young (median age 27 years, range 21 to 58 years) and had no comorbidity. We believe that the low CD4 and CD8 cell counts reflected the severity of infection due to the SARS virus and are therefore good markers of disease activity. Depletion of lymphocytes may be secondary to the direct effect of the virus on the lymphocytes or the effect of various cytokines.

Neutrophilia was also common among patients with SARS and might be related to treatment with corticosteroids, but our results implied that full sepsis work up and empirical broad spectrum antibiotics should be considered in patients with neutrophilia.

Thrombocytopenia followed by reactive thrombocytosis was another common finding in our study. Thrombocytopenia has been reported in a variety of viral infections. It may be caused by an immune mechanism or a direct effect of viruses on megakaryocytes or platelets. Megakaryocytes are capable of harbouring a variety of viruses, although the mechanism of viral entry into megakaryocytes is not well understood. Dysmorphic megakaryocytes containing

¶ Analysis performed in a subgroup of 31 patients.
Lymphopenia was common among patients with SARS. It was also found in various lymphoid tissues on postmortem examination and may be a marker of disease activity.

Both CD4 and CD8 lymphocyte counts decreased during the early course of SARS. Low CD4 and CD8 lymphocyte counts at presentation were associated with adverse outcomes.

Leucocytosis with neutrophilia, thrombocytopenia, and isolated prolonged activated partial thromboplastin time were common in patients with SARS.

inclusion bodies, vacuoles, degenerating nuclei, or showing naked nuclei may be seen in infected marrow. In most patients we found no evidence of disseminated intravascular coagulation. The postmortem findings of active bone marrow with normal megakaryocytes in patients with thrombocytopenia favour an immune cause of thrombocytopenia.

A major side effect of ribavirin is reversible haemolytic anaemia. About 60% of our patients who received ribavirin experienced a drop of haemoglobin of more than 20 g/L. Despite this high drop, ribavirin was well tolerated and none of the patients needed withdrawal of treatment or transfusion. The development of anaemia may be a cause for concern. None of the haemolysis was transient, and haemoglobin counts improved after treatment with ribavirin had been completed in all cases. Careful monitoring of haemoglobin is advisable for patients who receive ribavirin.

Conclusions

Lymphopenia, in particular T lymphopenia, was common among patients with SARS in our study. A notable drop in CD4 and CD8 lymphocyte counts occurred early in the course of the syndrome and was associated with adverse outcomes. Thrombocytopenia, neutrophilia, and transient prolonged activated partial thromboplastin time were other common findings. Further studies to evaluate the mechanisms of these manifestations may help us to understand this disease.

We thank the Haematology Division of the Department of Anatomical and Cellular Pathology for their full support in the laboratory investigations.

What is already known on this topic

Severe acute respiratory syndrome (SARS) is an emerging infection that is spreading worldwide.

The haematological features of this disease have not been described in detail elsewhere.

Previous studies have indicated that patients with SARS may develop lymphopenia and thrombocytopenia, but the significance of these findings is uncertain.

What this study adds

Lymphopenia was common among patients with SARS. It was also found in various lymphoid tissues on postmortem examination and may be a marker of disease activity.

Both CD4 and CD8 counts decreased during the early course of SARS. Low CD4 and CD8 lymphocyte counts at presentation were associated with adverse outcomes.

Leucocytosis with neutrophilia, thrombocytopenia, and isolated prolonged activated partial thromboplastin time were common in patients with SARS.
