Gastrointestinal symptoms were not prominent, and the excess in girls mirrors that seen in affected adults. The most striking observation was that children with IgA-EMA were shorter by more than 0.76 standard deviation scores and lighter by 0.54 standard deviation scores than antibody negative children matched for date and place of birth. This equates to about 9 months' growth and weight gain in an average child around this age. These features were independent of gastrointestinal symptoms and anaemia and presumably unrelated to malabsorption.

Occult celiac disease seems to start in childhood, even in those who are subsequently diagnosed as adults. The search for the trigger resulting in the breakdown of immune tolerance to gluten therefore needs to focus on infancy and intrauterine life.

We thank the children and their families taking part in the study for their continuing support and the midwives for their cooperation and help in recruitment. The ALSPAC study team comprised interviewers, computer technicians, clerical workers, research scientists, volunteers, and managers who continue to make the study possible.

Contributors: PJR, DJU, and AJKW designed the study with members of the ALSPAC study team. AJKW, RJL, and AJN developed and completed all antibody assays. RWJ coordinated the collection of biological samples and supervised handling of the samples. PJR analysed and interpreted the data with help from ARN. PJR wrote the report with help from the other authors. PJR is guarantor.

Funding: Coeliac UK, Medical Research Council, Wellcome Trust, UK government departments, and various charitable organisations and commercial companies. ALSPAC is part of the WHO initiated European Longitudinal Study of Pregnancy and Childhood.

Competing interests: None declared.

Ethical approval: ALSPAC ethics and law committee and local ethical research committees.

Use of tobacco products as dentifrice among adolescents in India: questionnaire study

D N Sinha, P C Gupta, M S Pednekar

In India legislation prohibits the use of tobacco as an ingredient in dental care products. Such products, in the form of powder or paste, are applied most commonly with the index finger to teeth and gums. Various tobacco products are used as dentifrice in different parts of India. We are not aware of any reports covering such a use of tobacco products (in contrast to chewing and smoking) especially among adolescents.

Participants, methods, and results

The global youth tobacco survey focuses on school students aged 13-15 and uses standardised methods. In India the survey is being conducted independently in each state. We report on the prevalence of the use of tobacco products as dentifrice in 14 states listed in the table, with sample sizes ranging from 2067 to 5245 students.

We selected a two stage probability sample of students in grade 8-10 (which corresponds to 13-15 years in age) in each state and conducted a survey among students with an anonymous, self administered, close ended questionnaire. Participants were asked to include a maximum of five products, which could differ from state to state. A pilot tested questionnaire for India contained a specific question on application of tobacco products (in addition to chewing), and a positive response identified the use of a tobacco product as dentifrice. We defined current use as use within 30 days preceding the survey.

The overall response rate was over 80% except in Bihar (70%) and Maharashtra (79%). The proportion of boys was between 50% and 55% in the different states.

The use of tobacco products as dentifrice varied from 6% (Goa) to 68% (Bihar). The prevalence among boys was notably higher than among girls in Orissa and Uttaranchal, marginally higher in nine states, and marginally lower in three states. Of the specific products, tobacco toothpaste (creamy snuff) and tooth powder (lal dant manjan) were common in all states (table). Gul (a pyrolysed tobacco product) was used in eight states. Other dentifrice products containing tobacco were mishri (roasted and powdered tobacco) and dry snuff (bajpur or takphi) in Goa and Maharashtra; gudakhu (paste of tobacco and molasses) in Bihar, Orissa, Uttar Pradesh, and Uttaranchal; and tobacco water (tulbur or hidakhu) manufactured by passing tobacco smoke through water) in Manipur, Mizoram, Sikkim, and Tripura. It is used for gargling, not drinking.

Comment

Many students in India use tobacco products as dentifrice. Differences between the sexes were minimal and presumably unrelated to malabsorption.

In India the misconception is widespread that tobacco is good for the teeth. In a study reported from Ernakulam district in Kerala 92% (3013) of 3261 female...
Blood pressure, haemorrhagic stroke, and ischaemic stroke: the Korean national prospective occupational cohort study

Yun-Mi Song, Joohon Sung, Debbie A Lawlor, George Davey Smith, Youngsoo Shin, Shah Ebrahim

Deaths from haemorrhagic stroke declined consistently through the 20th century, but deaths from ischaemic stroke showed a rise and fall, mirroring the coronary heart disease epidemic. Blood pressure has also declined, and if blood pressure is more strongly associated with haemorrhagic stroke than with ischaemic stroke, this might contribute to the divergent trends. Previous meta-analyses have shown contradictory findings; one showed similar associations for both stroke subtypes, and another, of Asian studies, showed a stronger association with haemorrhagic stroke than with ischaemic stroke. To resolve this uncertainty, we examined the association of blood pressure with subtype of stroke in a large cohort of Korean civil servants.

Participants, methods, and results

The Korean National Health System for public servants and teachers provides medical expenses and biennial multilocus health examinations at which blood pressure is measured in the seated position by trained staff using a standard mercury sphygmomanometer (fifth Korotkoff sound used for diastolic pressure) or an electronic manometer. We grouped mean blood pressures for individuals between 1986 and 1996 according to the joint national committee on prevention, detection, and treatment of high blood pressures for individuals between 1986 and 1996 (table). We included deaths attributed to ICD-10 (international classification of diseases, 10th revision) codes of I60-I69 for all strokes, I61 for haemorrhagic stroke, and I63 for ischaemic stroke: the Korean national prospective occupational cohort study.
