groups and adjust for clustering are likely to strengthen the findings presented here.

Conclusions

As expectations of continuing growth have evaporated in industrialised countries with the advent of the global economy, downsizing has become an increasingly important trend. This study indicates that downsizing may lead to elevated absence rates and increase cardiovascular mortality among people who remain employed. Policy makers, employers, and occupational health professionals should recognise that downsizing may pose a severe risk to health.

Ethical approval: The ethics committee of the Finnish Institute of Occupational Health approved the study.

Subjects, methods, and results

We used a case-control approach on data from a cohort that has been described previously. Briefly, we used the Universal Quebec Automobile Insurance Agency to identify all 224,734 drivers aged between 67 and 84 years in the province of Quebec at 1 June 1990 and followed them up to 31 May 1993. To be included in the cohort subjects needed to have a valid driver’s licence and to have lived in Quebec for at least two years before 1 June 1990. Cohort subjects were followed up until they reached the age of 85 or emigrated from Quebec or until 31 May 1993, whichever was the earliest. We defined the study outcome as subjects’ involvement, as drivers, in a motor vehicle crash in which at least one person sustained a physical injury. Cases were subjects who had any such crash during the follow up period, and the date of their first crash was taken as the index date. Controls were a 3% random sample of the cohort, and their index dates were randomly selected during the follow up.

Exclusion criteria were the same as in the previous study. We used data from the Quebec Health Insurance Agency to identify subjects’ use of prescription drugs and other covariate information. The database on prescription drugs includes information on all outpatient prescriptions of drugs dispensed to people aged 65 years or older. The accuracy and validity of these data have been shown to be high.

We used logistic regression to compute the odds ratio as an estimate of the rate ratio of an injurious motor vehicle crash during the follow up period, and the date of their first crash was taken as the index date. Controls were a 3% random sample of the cohort, and their index dates were randomly selected during the follow up. Exclusion criteria were the same as in the previous study. We used data from the Quebec Health Insurance Agency to identify subjects’ use of prescription drugs and other covariate information. The database on prescription drugs includes information on all outpatient prescriptions of drugs dispensed to people aged 65 years or older. The accuracy and validity of these data have been shown to be high.

We used logistic regression to compute the odds ratio as an estimate of the rate ratio of an injurious motor vehicle crash associated with use of lithium or carbamazepine. We defined exposure to the drugs as any prescription in the year before the index date and current use as a prescription dispensed in the 60 days before the index date. We adjusted for age, sex, place of residence (urban or rural), previous involvement in an

Use of lithium and the risk of injurious motor vehicle crash in elderly adults: case-control study nested within a cohort

Mahyar Etminan, Brenda Hemmelgarn, J A C Delaney, Sany Sissa

Since its introduction in the 1960s lithium has been an effective agent for stabilising mood in the treatment of bipolar disorder. However, its use has been linked to impaired memory and slow reaction times.1 Car crashes resulting from drug use are becoming a major public health hazard among elderly people. We assessed the association between elderly people’s use of lithium and their involvement in motor vehicle crashes. We also assessed another common mood stabiliser, carbamazepine, which has a different mechanism of action to lithium.

Subjects, methods, and results

We used a case-control approach on data from a cohort that has been described previously. Briefly, we used the Universal Quebec Automobile Insurance Agency to identify all 224,734 drivers aged between 67 and 84 years in the province of Quebec at 1 June 1990 and followed them up to 31 May 1993. To be included in the cohort subjects needed to have a valid driver’s licence and to have lived in Quebec for at least two years before 1 June 1990. Cohort subjects were followed up until they reached the age of 85 or emigrated from Quebec or until 31 May 1993, whichever was the earliest. We defined the study
injurious motor vehicle crash, chronic disease score, and exposure to central nervous system drugs in the 60 days before the crash.

A total of 5579 people in the cohort had an injurious motor vehicle crash during the follow up period. A random sample of 13 300 control subjects was drawn from the cohort. Current use of lithium was higher among subjects who had been involved in an injurious motor vehicle crash than among control subjects (rate ratio 2.08 (95% confidence interval 1.11 to 3.90) (table 1). Current use of carbamazepine was not associated with having had an injurious motor vehicle crash (rate ratio 0.83 (0.48 to 1.44)).

Comment

Elderly people who use lithium may increase by twofold the risk of being involved in an injurious motor vehicle crash while driving. We had no information on diagnoses of bipolar disorder in this group (including severity of disease). Our sample size was too small to allow stratification by number of drugs used. There may, therefore, have been a small possibility in our study of confounding by indication due to disease severity.

A recent retrospective cohort study found lithium to be more efficacious than valproate semisodium (divalproex sodium) in preventing suicides.1 Finding may prompt clinicians to favour lithium over other mood stabilising agents. Patients who are prescribed lithium must be told about the increased risk of motor vehicle crashes.

A memorable patient

Aggie

I will call her Agatha Radcliffe, though that is not her real name. Nor was she my patient. I was on rota duty on a freezing, wintry Saturday night some time in the 1950s. The day had been long and arduous, and, at about 11 o’clock, having just got home from another visit, I received an urgent call to visit a Miss Radcliffe, who was having an asthma attack.

It didn’t take long to get to her house. She was sitting up in bed, her head between her hands with her elbows resting on her knees, gasping. No stethoscope was needed to hear the shilliant ronchi. She was in her 70s, a frail spinster with white hair, weighing no more than eight stone, and with rather fine chiselled features. She had obviously been very beautiful when she was young. I wanted to give her an injection of aminophylline but had none with me, so I told her that I would get some from my surgery, which was less than a mile away, and she seemed to be satisfied when I assured her that I would be back soon.

As I slowly injected the aminophylline, I said, “You don’t know me do you?”

“You’re Hyman Davies,” came the prompt reply.

“That you recognise me when I first came into the house?”

“Oh of course I did.”

“Then why didn’t you tell me?”

“I was waiting to see if you would recognise me,” she answered.

“Of course I did.”

I lay waiting for a good job for a fine lady, albeit a tiny reward for what she had done for me.

To see Aggie again made me do a good job for a fine lady, albeit a tiny reward for what she had done for me. Hyman Davies retired general practitioner, Prestwich, Manchester.
