Norway's new principles for primary prevention of cardiovascular disease: age differentiated risk thresholds

A mishap during editing caused the deletion of the first digit in each item of a bulleted list, leading to an overenthusiastic interpretation of Norway's recommendations for preventive drug treatment in this article by Ole Frithjof Norheim and colleagues (*BMJ* 2011;343:d3626, doi:10.1136/bmj.d3626). The correct age groups for drug treatment are

- 40–49 years: if 10 year risk of cardiovascular death is $\geq 1\%$
- 50–59 years: if 10 year risk of cardiovascular death is $\geq 5\%$
- 60–69 years: if 10 year risk of cardiovascular death is $\geq 10\%$.
