Abstract

Objective To evaluate the impact of the Cleanyourhands campaign on rates of hospital procurement of alcohol hand rub and soap, report trends in selected healthcare associated infections, and investigate the association between infections and procurement.

Design Prospective, ecological, interrupted time series study from 1 July 2004 to 30 June 2008.

Setting 187 acute trusts in England and Wales.

Intervention Installation of bedside alcohol hand rub, materials promoting hand hygiene and institutional engagement, regular hand hygiene audits, rolled out nationally from 1 December 2004.

Main outcome measures Quarterly (that is, every three months) rates for each trust of hospital procurement of alcohol hand rub and liquid soap; *Staphylococcus aureus* bacteraemia (meticillin resistant (MRSA) and meticillin sensitive (MSSA)) and *Clostridium difficile* infection for each trust. Associations between procurement and infection rates

assessed by mixed effect Poisson regression model (which also accounted for effect of bed occupancy, hospital type, and timing of other national interventions targeting these infections).

Results Combined procurement of soap and alcohol hand rub tripled from 21.8 to 59.8 mL per patient bed day; procurement rose in association with each phase of the campaign. Rates fell for MRSA bacteraemia (1.88 to 0.91 cases per 10 000 bed days) and *C difficile* infection (16.75 to 9.49 cases). MSSA bacteraemia rates did not fall. Increased procurement of soap was independently associated with reduced *C difficile* infection throughout the study (adjusted incidence rate ratio for 1 mL increase per patient bed day 0.993, 95% confidence interval 0.990 to 0.996; P<0.0001). Increased procurement of alcohol hand rub was independently associated with reduced MRSA bacteraemia, but only in the last four quarters of the study (0.990, 0.985 to 0.995; P<0.0001). Publication of the Health Act 2006 was strongly associated with reduced MRSA bacteraemia (0.86, 0.75 to 0.98; P=0.02) and *C difficile* infection (0.75, 0.67 to 0.84; P<0.0001). Trust visits by

Web appendix: Supplementary information

Department of Health improvement teams were also associated with reduced MRSA bacteraemia (0.91, 0.83 to 0.99; $P=0.03$) and *C difficile* infection (0.80, 0.71 to 0.90; $P=0.01$), for at least two quarters after each visit.

Conclusions The Cleanyourhands campaign was associated with sustained increases in hospital procurement of alcohol rub and soap, which the results suggest has an important role in reducing rates of some healthcare associated infections. National interventions for infection control undertaken in the context of a high profile political drive can reduce selected healthcare associated infections.

Introduction

Healthcare associated infections can spread from patient to patient through the contamination of healthcare workers' hands by infectious organisms.¹ Improving hand hygiene reduces infection in a wide variety of settings.^{2,3} Following government and public concern at reported high levels of meticillin resistant *Staphylococcus aureus* (MRSA) bacteraemia, meticillin sensitive *S aureus* (MSSA) bacteraemia, and *Clostridium difficile* infection,^{4,6} and low levels of hand hygiene compliance,^{7,9} the Cleanyourhands campaign¹⁰ was rolled out in 2004 in England and Wales to healthcare workers in all acute National Health Service (NHS) hospital trusts.

The main components of the campaign comprised provision of alcohol hand rub at the bedside, distribution of posters reminding healthcare workers to clean their hands, regular audit and feedback of compliance, and provision of materials empowering patients to remind healthcare workers to clean their hands. Trusts were to order soap and alcohol hand rub through the central NHS supply agencies, which had ensured that all products met efficacy, safety, and acceptability standards. The campaign was centrally funded by the Department of Health and coordinated by the National Patient Safety Agency, which rolled out the campaign to all acute trusts from December 2004 to June 2005. The campaign was refreshed at the end of June 2006,¹¹ and relaunched with new posters in October 2007. The development, roll out, and long term coordination of the campaign is described in full elsewhere.¹⁰⁻¹²

Although the main components of the campaign were interventions reported to be effective at the level of the single hospital or individual unit,¹³⁻¹⁵ such interventions had not previously been implemented or evaluated at a national level.¹⁶ The Department of Health funded an independent evaluation of the campaign, which faced methodological challenges common to other recent studies evaluating large scale public health interventions.^{17,18} Firstly, the policy requirement to roll out the campaign quickly precluded the use of randomised or stepped wedge designs and prevented collection of data that were not routinely available, such as hand hygiene compliance. Secondly, other national interventions or initiatives that were not planned or anticipated at the start of the study but which targeted reduction of MRSA bacteraemia or *C difficile* infection were implemented during the study. These interventions included the Saving Lives campaign (a programme of implementing infection control care bundles within a clinical governance framework),¹⁹ the setting of a national target for MRSA bacteraemia, publication of the Health Act 2006 (legislation of statutory criteria for infection control),²⁰ and visits to trusts by Department of Health improvement teams to reinforce delivery of the Saving Lives campaign (table 1⇓).

To meet these challenges, the study used a prospective, ecological, time series design, suitable for evaluating public health interventions,²¹ using existing trust level data for the main outcomes and measurement of potential confounders. Because

of the absence of data for hand hygiene compliance, we used available trust level data for procurement of alcohol hand rub and soap as a proxy. These data are considered a more practical and objective way to assess quantitative change in hand hygiene between hospitals²² and better indicate 24 hour, seven day a week use of alcohol hand rub and soap.^{23,24} In addition, the original study on which the campaign was based had shown a rise in both compliance and procurement.¹⁴ We dealt with the potentially confounding effects of other national interventions by collecting available trust level information on these interventions to incorporate into the overall analysis.

We aimed to assess the Cleanyourhands campaign's impact on hospital procurement of soap and alcohol hand rub, to report on trends in rates of MRSA and MSSA bacteraemia and *C difficile* infection, and to determine an association between infection and procurement rates.

Methods

Study design, phases, and setting

We used a prospective, ecological, interrupted time series design that routinely collected data at the trust level. The study was designed and reported according to standard guidelines for infection control interventions.²⁵ The campaign was applied to the first six trusts in December 2004 and to the remaining 181 by the end of June 2005 in four waves (table 1). Since the campaign was applied to so few trusts in December 2004 (most of which had been involved in the national pilot study¹⁵), national roll out was considered to have begun on 1 January 2005, with the study divided into three predefined phases: 1 July 2004 to 31 December 2004 (six months before roll out of the campaign), 1 January to 30 June 2005 (campaign roll out), and 1 July 2005 to 30 June 2008 (36 months after roll out of the campaign).

Outcome measures

Monthly procurement data (volume, mL) for alcohol hand rub and liquid soap for each individual trust served as a proxy marker for usage and compliance. We collected this information prospectively from central suppliers in England (NHS Supply Chain) and Wales (Welsh Health Supplies), and smoothed out the effects of procurement spikes due to infrequent bulk ordering (see below).

To record infection rates, the study had access to the database for the national mandatory reporting scheme in England, held by the Health Protection Agency. This database categorised hospital trusts as acute, teaching, or specialist. It also collected count data every quarter (or three months) for hospital acquired (that is, >48 h after admission) MRSA bacteraemia (at all ages), *C difficile* infection (at age ≥ 65 years), and MSSA bacteraemia (although MSSA data were not differentiated into hospital acquired and community acquired categories). We did not use data for Welsh hospitals because it was not possible to separate data for acute trusts from those for primary care and community hospitals.

For each trust, we estimated the total number of occupied bed days for each month or quarter using national KH03 data. Since data for *C difficile* infection rates were only for patients older than 65 years, we could use these data to provide only an estimate of incidence, because the KH03 data used were not age related.

In relation to potential confounders during the study period, other mandatory national interventions were introduced that targeted the same infections as the Cleanyourhands campaign (table 1). The study recorded the dates of the announcement of

the MRSA target, and of publication of the Health Act 2006²⁴ and the individual care bundles for the Saving Lives campaign, and the date that each individual trust registered with the Saving Lives campaign and received visits by a Department of Health improvement team. We collected trust level data for mupirocin use, a surrogate marker for MRSA screening and decolonisation, via Intercontinental Marketing Services Health for Trusts. Data for average length of stay were obtained from hospital episode statistics.

Statistical analysis

Smoothed trends in monthly procurement data were estimated by applying a series of median smoothers to the time series of alcohol hand rub and soap for each trust, and expressed as mL per patient bed day for soap, alcohol hand rub, and both in each quarter. We excluded 23 trusts that had a sequence of at least 18 months with missing data, and 44 trusts that had at least two years of missing soap data or were supplied by another source. We assessed temporal trends in a mixed effects, linear regression analysis with usage per bed day as the outcome variable. We used the Cleanyourhands campaign's roll out, year 2 refreshment of the campaign, year 3 relaunch, and quarter as fixed effects and the trust as a random effect. The associations between procurement rates and improvement team visits (differentiating between visits for MRSA bacteraemia and *C difficile* infection) or publication of the Health Act 2006 were assessed, accounting for temporal trends in procurement and trust type.

We expressed trends in quarterly infection rates as cases per 10 000 patient bed days for 170 English acute trusts, excluding five because mergers and reorganisations disrupted continuity of data. Four children's trusts were excluded from the *C difficile* infection rates because their patients were too young.

The quarterly counts of incident infections were used as the outcome variables in a series of mixed effects Poisson regression models to assess the associations with estimated concurrent procurement of hand hygiene consumables. We assessed the consistency of the associations between infections and consumables by incorporating an interaction between quarters and consumables, and included the potential confounders (listed above) as fixed effects. To allow for a lag in the effectiveness in some of the above interventions, we categorised the data to include periods immediately before and after intervention. We included the quarter and trust in the regression models as random effects, to allow for temporal trends. The natural logarithm of the estimated number of occupied beds was used as an offset in the regression model to directly obtain estimates of incidence rate ratios. We fitted all models to the data using the `xtmepoisson` command within Stata 11. The effect of trust type on the procurement association was explored using a three way interaction (type, procurement, quarter).

Results

Trends in procurement of alcohol hand rub and soap

Average procurement of alcohol hand rub rose throughout the study, from 3.4 to 26.0 mL per patient bed day but not at the expense of soap procurement, which also rose from 17.4 to 33.8 mL per patient bed day (fig 1). Combined procurement almost tripled, from 21.8 to 59.8 mL per patient bed day. The regression model showed that the rate of change increased significantly during the roll out of the Cleanyourhands campaign (average absolute increase in procurement per quarter 1.83 (95% confidence interval 1.60 to 2.07) for alcohol hand rub, 0.99 (0.41 to 1.56) for soap), after campaign refreshment (1.4 (1.10

to 1.70), 1.22 (0.38 to 2.07)), and after campaign relaunch (1.28 (1.16 to 1.41), 1.08 (0.69 to 1.48)). The average increase in procurement of alcohol hand rub was notably higher than that of soap only in the rollout phase.

Trends in infection rates

Data were available from 170 trusts for MRSA bacteraemia and from 165 for MSSA bacteraemia and *C difficile* infection. The rate of MRSA bacteraemia fell from a peak of 1.88 to 0.91 cases per 10 000 bed days (fig 2). Funnel and scatter plots showed no evidence of particular trusts making disproportionately large contributions to the fall (web appendix). The MSSA bacteraemia rate rose slightly from 2.67 per 10 000 bed days to a peak of 3.23, before falling to 3.0 at the end of the study. The estimated rate of *C difficile* infection fell from a peak of 16.75 to 9.49 cases per 10 000 bed days, being subject initially to seasonal peaks in the first quarter of each year, which disappeared in the last year of the study (fig 3).

Associations between infection and procurement rates

Procurement data for alcohol hand rub and soap from 116 trusts were collected, and contributed 1727 quarters of observations to the model for MRSA bacteraemia, with 115 and 112 trusts contributing 1685 and 1658 quarters of observations, respectively, to the models for MSSA bacteraemia and *C difficile* infection, respectively. The remaining quarters had at least one predictor variable missing.

We found a significant independent association between soap procurement and *C difficile* infection throughout the study, with each additional mL of soap per patient bed day associated with a 0.7% (95% confidence interval 4% to 10%) reduction in *C difficile* infection ($P < 0.0001$; table 2). Thus, for an increase of 10 mL in soap procurement per bed day, the estimated incident rate ratio would be 0.993 (95% confidence interval 0.99 to 0.996)¹⁰, which is 0.929 (0.904 to 0.961) or a 7.1% (3.9% to 9.6%) relative reduction in infection rates. This association did not change with time, after comparing overall estimates in each of the four years of the study (likelihood ratio test; $\chi^2 = 1.89$, $df = 3$, $P = 0.6$).

Each additional mL of alcohol hand rub procured per patient bed day was associated with a rise in *C difficile* infection which changed over time, being most marked during periods of high incidence of *C difficile* infection. Further analyses showed strong correlations between soap and alcohol hand rub procurement (web appendix). When included separately in a simplified model, each consumable was associated with a reduction in *C difficile* infection. Inclusion of both consumables removed the association with alcohol hand rub, suggesting that only soap was independently associated with reduced *C difficile* infection.

The association of alcohol hand rub with MRSA bacteraemia changed over time, becoming significant only in each of the last four quarters of the study (fig 4), with an estimated reduction in MRSA bacteraemia of 1% (95% confidence interval 5% to 15%) for each additional mL used per bed day (table 3). Thus, for every increase in alcohol hand rub procurement of 10 mL per bed day, the estimated incident rate ratio would be 0.99 (0.985 to 0.995)¹⁰, which is 0.904 (0.857 to 0.951) or a 9.6% (4.9% to 14.3%) relative reduction in infection rates.

Although MSSA bacteraemia was not associated with alcohol hand rub procurement, we saw a significant association between increasing use of liquid soap and increasing MSSA bacteraemia (incident rate ratio 1.0029 (95% confidence interval 1.001 to 1.004); $P = 0.0001$), for each extra mL of soap used per bed day,

which could have been due to collinear increasing temporal trends. Publication of the Health Act 2006 was strongly associated with reductions of both MRSA bacteraemia and *C difficile* infection, as were Department of Health improvement team visits, two or more quarters after each visit (tables 2 and 3). We saw no associations between these visits and procurement rates. Publication of the Health Act 2006 was associated with a significant increase in the procurement rate of alcohol hand rub (0.68 mL per bed day (95% confidence interval 0.37 to 0.99)) and soap (1.055 (0.32 to 1.79)), after comparing the average quarterly rate of rise in mL per bed day in the period after the roll out (but before publication of the act) with the period after publication of the act.

We found no other associations of infection rates with procurement data, phases of the campaign, or any other intervention or potential confounder, with the three way interaction between trust category, procurement data, and quarter proving non-significant for MRSA bacteraemia ($\chi^2=37.70$, $df=30$, $P=0.16$) or *C difficile* infection ($\chi^2=25.54$, $df=16$, $P=0.06$). Evidence suggested some selection bias—that is, trusts with missing data for soap had lower rates of MRSA bacteraemia (0.92, 95% confidence interval 0.85 to 0.98) and *C difficile* infection (0.88, 0.86 to 0.90) and higher rates of MSSA bacteraemia (1.082, 1.04 to 1.13). Trusts with missing data for alcohol hand rub had lower rates of *C difficile* infection (0.58, 0.54 to 0.63). We found no selection bias in the type of trust.

Discussion

The study has shown that increasing procurement of alcohol hand rub and soap was associated with each phase of the Cleanyourhands campaign and that rates of MRSA bacteraemia and *C difficile* infection fell while rates of MSSA bacteraemia rose. We found strong independent associations between increasing soap procurement and falling *C difficile* infection rates throughout the study, and between increasing procurement of alcohol hand rub and falling rates of MRSA bacteraemia in the last year of the study. Increasing procurement was not the sole driver of these reductions, because publication of the Health Act 2006 and improvement team visits were both strong independent factors.

Strengths and limitations of the study

The strengths of the study were the inclusion of all trusts nationally over four years, including the period covering all phases of the campaign, collection of standardised objective proxy measures of hand hygiene (procurement of alcohol hand rub and soap), standardised collection of outcome data for key infections through national surveillance data, collection of potential confounding variables including the introduction and timing of other infection control interventions, and an appropriate analysis allowing control of confounding at trust level (instead of national level) to identify independent associations between use of hand hygiene consumables and hospital acquired infections.

Limitations of the study included the policy imperative to roll out the intervention quickly, which precluded more robust designs and the collection of potentially important but unavailable trust level data—in particular, antibiotic prescription and direct measures of hand hygiene compliance. However, although antibiotic data might confound reported associations between procurement and infection, it would require a strong correlation between rises in procurement and decreases in selected antibiotics to abolish these strong independent associations. Although procurement is only a proxy for hand

hygiene compliance, nevertheless it is an objective measure collected in a comparable manner through NHS procurement across almost all trusts. Therefore, this objectivity minimises potential for observer bias and sampling bias, which are well recognised limitations of direct observation of hand hygiene compliance.²²⁻²⁴ Data were available from 87% and 74% of trusts for alcohol hand rub and soap, respectively, allowing for inclusion of the great majority of trusts in the analyses, which would have been difficult to achieve practically, through standardised measures of directly observed hand hygiene. The missing data would probably not have affected the trends and associations reported in the study.

Impact of campaign on procurement of alcohol hand rub and soap

Procurement of both alcohol hand rub and soap rose significantly in association with each phase of the campaign, the effect being greater for alcohol hand rub in the rollout phase, possibly indicating that campaign documents and guidance¹⁰ targeted use of the consumable, with few references to soap.²⁶

A possible reinforcer of this effect is the publication of the Health Act 2006, which imposed legally binding duties on trusts, including provision of “adequate hand washing facilities and hand rubs,” and mandated a rolling audit programme on hand hygiene that was embedded in local clinical governance frameworks. However, the increase in procurement of both alcohol hand rub and soap associated with the Health Act 2006 was either less than, or the same order of magnitude as, that associated with each campaign phase, and the act was published close to the final phase of the campaign. Therefore, the campaign could plausibly be interpreted as the main overall driver for the sustained increase in procurement, especially because the improvement team visits had no effect on this at individual trust level. This interpretation is consistent with findings from the National Audit Office that three years after completion of campaign roll out, 90% of acute trusts considered the campaign a top priority, with most of its main components implemented in nearly all wards.²⁷

Associations between procurement and infection data

We found strong independent associations between increasing soap procurement and falling *C difficile* infection rates throughout the study, and between increasing alcohol hand rub and falling MRSA bacteraemia rates in the last year of the study. These associations remained after adjustment for all other measured interventions and variables, and are biologically plausible and consistent with epidemiological models.²⁸⁻³¹ The delayed association between procurement of alcohol hand rub and MRSA bacteraemia merits further investigation. The association might relate to a possible non-linear association between hand hygiene and MRSA prevalence,^{28 29} or to long term changes in the community reservoir of MRSA carriage resulting from the intervention.^{30 31} Other intervention studies^{32 33} have also reported possible threshold effects for hand hygiene compliance. The lack of association between MRSA bacteraemia and soap procurement could indicate the fact that soap is a less effective disinfectant than alcohol hand rub for *S aureus*. The association between higher soap procurement and lower *C difficile* infection is consistent with the removal of *C difficile* spores by soap and water, but not by alcohol hand rub.³⁴

The lack of association between procurement data and MSSA bacteraemia^{28 29 33} could indicate that hand hygiene is less effective at interrupting endogenous transmission of infection

(which is more likely for MSSA), than at interrupting the exogenous transmission (which in hospital settings is more likely to be associated with MRSA). The finding that non-specific interventions, such as hand hygiene, are more effective at reducing resistant rather than susceptible organisms when resistance is rare in the community is also consistent with predictions from mathematical models.³⁵ The rise in MSSA bacteraemia during the study may reflect a generalised increase in community acquired staphylococcal infections reported in England³⁶ and elsewhere.³⁷ A high proportion of these bacteraemias are community acquired³⁸ and thus less amenable to hospital based interventions. Notably, it was not possible with the available data to distinguish between hospital acquired and community acquired MSSA bacteraemia.

National infection control interventions

Increasing procurement was not the sole driver for the reductions in *C difficile* infection and MRSA bacteraemia, because publication of the Health Act 2006 and trust visits by improvement teams were both strongly independently associated with the same reductions. Although our analysis controlled for these interventions, we cannot completely disentangle the relative effects through an observational study, a common problem when assessing the effectiveness of public health interventions in the real world.^{17 18} The campaign took place within the context of a high profile political drive and other national interventions to reduce MRSA and *C difficile* in particular. The campaign received central sustained funding and coordination. Government support for such campaigns has been identified as important elsewhere in Europe.^{22 39 40} The Cleanyourhands campaign was the first national campaign on hand hygiene in the world, and the World Health Organization currently offers a very similar intervention as part of its Save Lives initiative.^{41 42} Although caution should be exercised when extrapolating from the current study, its findings suggest that the campaign could offer a model for other countries to adopt or adapt.

Indeed, several evaluations at smaller scales of similar campaigns have found improved compliance to hand hygiene, increased procurement of alcohol hand rub, and an association of alcohol hand rub with MRSA reduction.^{14 43-47} However, comparison with the existing scientific literature is difficult because this is the first national study of this size and duration, with this number of infection outcomes, that has considered hospital procurement of both soap and alcohol hand rub and has attempted to relate procurement to infection, accounting for multiple potential confounders.

Research and policy implications

This study, similar to other recent evaluations of public health interventions on a large scale,^{17 18} has implications for the design of future studies. Evaluation is essential but needs funding and considerable planning, to balance the competing needs of implementation and evaluation.¹⁸ Consideration should be given to staggering the roll out of interventions to facilitate higher quality designs⁴⁸ and to extending national reporting to procurement and antibiotic prescribing data¹⁶ and to an increased range of infections.²⁷ These factors would provide an improved infrastructure for future prospective evaluations of national interventions on infection control.

In conclusion, this study has shown that the national Cleanyourhands campaign was associated with increased procurement of alcohol hand rub and soap in each phase of the campaign. Higher procurement of soap and alcohol hand rub,

publication of the Health Act 2006, and Department of Health improvement team visits to individual trusts were all strongly independently associated with reductions in MRSA bacteraemia and *C difficile* infection. The relative contribution of soap and alcohol hand rub to these reductions is unclear, but their strong and independent associations remained after adjustment for all other interventions. The study suggests that national infection control interventions, including a hand hygiene campaign, undertaken in the context of a high profile political drive, can successfully reduce selected healthcare associated infections.

We thank Richard Horsfall (NHS Supply Chain), Tracey Prothero (Welsh Health Supplies, NHS Wales), Peter Phillips (Intercontinental Marketing Services), Ginny Edwards (UK Department of Health), infection control teams in all English and Welsh acute trusts, Katherine Wilson (National Patient Safety Agency), and the two referees for their helpful comments on the paper.

Contributors: All authors read and had input in the final version of the paper; had access to the data and analyses; and were involved in the conception, design, and conduct of the study over four years, and interpretation of the data. CF wrote the first draft of the manuscript. CF and JS collected and organised data with help from AC, MM, and GD. AC did the data analysis with support from CF, JS, and SM. SPS wrote the original grant with input from AH, BCooper, BCooper, GD, AC, LT, AJ, SM, and JR.

Funding: The study received funding from the Patient Safety Research Programme (with donations from the trustees of the Royal Free London NHS Foundation Trust) and sponsorship from University College London. The funder had no role in the design, conduct, or analysis of the study.

Competing interests: All authors have completed the Unified Competing Interest form at www.icmje.org/coi_disclosure.pdf (available on request from the corresponding author) and declare: the study received funding from the Patient Safety Research Programme (with donations from the trustees of the Royal Free London NHS Foundation Trust) and sponsorship from University College London; no financial relationships with any organisations that might have an interest in the submitted work in the previous 3 years; no other relationships or activities that could appear to have influenced the submitted work.

Ethical approval: The study protocol was approved by the multicentre research ethics committee (04MRE/10/66 Scotland).

Data sharing: Databases from the study are described on the website of the National Observation Study of the Effectiveness of the Cleanyourhands Campaign, with which data sharing arrangements can be entered into. The Infectious Diseases Research Network has agreed to facilitate this sharing of data, thus reaching a wider audience within the infection control research community.

What is already known on this topic

Hand hygiene campaigns aim to reduce healthcare associated infections through sustained improvements in hand hygiene, although it is not known whether national campaigns are effective

The English and Welsh Cleanyourhands campaign was rolled out to all acute NHS trusts from January 2005, to reduce high levels of *Staphylococcus aureus* bacteraemia and *Clostridium difficile* infection

What this study adds

Each phase of the Cleanyourhands campaign was associated with increased hospital procurement of both alcohol hand rub and soap over a four year period

Increased procurement was strongly independently associated with reduced rates of methicillin resistant *S aureus* bacteraemia and *C difficile* infection, as were publication of the Health Act 2006 and trust visits by Department of Health improvement teams. These associations remained after adjustment for other interventions

Tables

Table 1 | Phases and key components of the Cleanyourhands campaign, and timing of other national interventions for infection control

Cleanyourhands campaign*	Other national interventions
Phase 1: before roll out (1 July to 31 December 2004)	
September 2004: patient safety alert issued, mandating placement of bedside alcohol hand rub	—
Phase 2: roll out (1 January to 30 June 2005)	
Roll out of campaign in four waves (January, March, April, June)	June 2005: Saving Lives campaign† launched
Phase 3: after roll out (1 July 2005 to 30 June 2008)	
End of June 2006: campaign refreshed, with maintenance handbook reiterating main components of campaign, increased emphasis on auditing and feedback, use of soap for <i>C difficile</i> infection, and further guidance on institutional engagement	July 2005 onwards: acute hospitals register set up for Saving Lives campaign November 2005: National target‡ for MRSA bacteraemia announced April 2006 onwards: acute hospital visits§ by improvement teams from the Department of Health October 2006: Health Act 2006¶ passed by parliament
October 2007: campaign year 3 relaunched, with new posters designed in collaboration with infection control teams	—

*National campaign implemented in 187 acute trusts in England and Wales, comprising placement of alcohol hand rub at patient's bedside, use of ward posters and patient empowerment materials, regular audits, and institutional engagement.

†Delivery programme designed to support acute hospitals in reducing common healthcare associated infections, by using a care bundle embedding infection control within a clinical governance framework (www.clean-safe-care.nhs.uk).

‡Target of 50% reduction in MRSA bacteraemia, to be achieved by each acute hospital over three years.

§Tailored support package to help hospitals deliver Saving Lives campaign and ensure that ultimate responsibility for healthcare associated infections lies with the chief executive. Although 103 hospitals were targeted because of high or rising levels MRSA bacteraemia or *C difficile* infection, or probable failure to achieve MRSA bacteraemia target, a further 50 hospitals requested a visit.

¶Legislation setting statutory criteria by which managers, chief executives, and boards ensure prevention and control of healthcare associated infections.

Table 2| Associations from Poisson mixed effects model for *C difficile* infections

Predictor	Estimated incidence rate ratio (95% CI)	P
Procurement rate		
Soap (per mL per bed day)	0.993 (0.990 to 0.996)	<0.0001
Alcohol hand rub (per mL per bed day)	1.010 (1.006 to 1.013)	<0.0001
Improvement team visit (for <i>C difficile</i> infection)		
Previous quarters	Reference	—
Quarter before visit	0.97 (0.81 to 1.16)	0.01
Quarter of visit	0.96 (0.79 to 1.15)	
Quarter after visit	0.90 (0.74 to 1.10)	
Subsequent quarters	0.80 (0.71 to 0.90)	
Publication of Health Act 2006	0.75 (0.67 to 0.84)	<0.0001

Table 3| Associations from Poisson mixed effects model for mandatory MRSA bacteraemia

Predictor	Estimated incidence rate ratio (95% CI)	P
Procurement rate of alcohol hand rub (per mL per day)		
July 2004 to June 2005	1.005 (0.999 to 1.012)	<0.0001
July 2005 to June 2006	1.003 (0.998 to 1.008)	
July 2006 to June 2007	1.002 (0.997 to 1.008)	
July 2007 to June 2008	0.990 (0.985 to 0.995)	
Improvement team visit (for MRSA bacteraemia)		
Previous quarters	Reference	—
Quarter before visit	1.07 (0.98 to 1.17)	0.03
Quarter of visit	1.00 (0.91 to 1.11)	
Quarter after visit	1.02 (0.92 to 1.13)	
Subsequent quarters	0.91 (0.83 to 0.99)	
Publication of Health Act 2006	0.86 (0.75 to 0.98)	0.02

Figures
