

ANALYSIS

SPOTLIGHT: PATIENT CENTRED CARE

Patient reported outcome measures in practice

Scores of tools to measure outcomes that matter to patients have been developed over the past 30 years but few are used routinely at the point of care. **Nelson and colleagues** describe examples where they are used in primary and secondary care and argue for their wider uptake to improve quality of care

Clinicians' understanding of the effect of disease and treatment on patients' daily lives is poor.¹ In response to this problem, over the past three decades, hundreds of standardised measures have been developed to capture patient reported outcomes, including symptom status, physical function, mental health, social function, and wellbeing. However, the patient reported outcome measures (PROMs) movement has largely been driven by the agenda of researchers or service payers and has failed to focus effectively on improving the quality of care from the patient's perspective (box 1). We use two examples to show how the use of PROMs in everyday practice has the potential to narrow the gap between the clinician's and patient's view of clinical reality and help tailor treatment plans to meet the patient's preferences and needs.²

Barriers to routine use

Evidence shows that the systematic use of information from PROMs leads to better communication and decision making between doctors and patients and improves patient satisfaction with care.³⁻⁷ There is also evidence that patients report better outcomes—for example, improvement in depression.⁸ However, research on attempts to embed measurement of patient reported outcomes into routine practice has revealed many technical, social, cultural, legal, and logistical barriers to successful adoption.⁹⁻¹³

Clinicians are often reluctant to use PROMs routinely because they fear it will add to their workload rather than make them more efficient and effective. Furthermore, many clinicians who do spend time talking to patients contend that they already understand their patients' problems and do not need additional information from them.

Patients generally welcome systems that routinely use PROMs. However, they say that patient reporting systems must be used well and not misdirect the focus of the clinical encounter, burden patients, or focus only on factors that have value to clinicians (box 2).

Any system designed to assess and respond to patient reported outcomes must include relevant and validated measures. These must be analysed and reported appropriately and the response to them made explicit in the notes. Identifying the best way to incorporate PROMs in pre-existing medical record systems while safeguarding privacy is challenging. The best design will vary for different patient populations, practice types, and clinical settings.

Below we present two cases from Sweden and the United States that show routine use of PROMs in primary and secondary care. Both systems were developed by experienced, practising physicians and share similar objectives but the design differs.

Swedish rheumatology quality registry

The Swedish rheumatology quality registry was established in 1995 and contains data on over 66 000 patients, about 85% of people in Sweden with rheumatoid arthritis.¹⁴ Data generated by patients is fed into a user friendly "dashboard" and used to support care. Patient reported outcome measures are tracked over time in relation to ongoing treatment. Patients input information on both disease specific and general measures of function and health, helping clinicians to provide more appropriate and patient centred care. The dashboard displays trends and is used to guide treatment, shared decision making, and self management. Experience suggests that the registry

Healthcare provider organisation

- Benchmarking
- Quality improvement

Clinical trials

- Screening
- Treatment outcomes

Clinical practice

- Diagnosis
- Monitoring progress

Information for patients or clinicians

- Choice of provider
- Choice of treatment

Box 2: Views of patient advocates

For most patients there is no systematic or effective method for communicating what happens outside the clinical encounter, such as perceived needs, symptoms, response to treatment, undesirable side effects, effect on function, and what matters to patients and their families. Like clinicians, patients want better outcomes for individuals and communities, and better professional development and system performance, although we might not use those same words to describe them.

PROM systems have the potential to enable improvement by providing information that can bridge the gap between the clinical reality and the patient world, triggering learning as well as the right next action.

PROM systems must be codeveloped by patients, the public, and professionals to obtain maximum value. They should be integrated with the rest of the patients' healthcare information and patients should be able to use the information when and where they choose, including for research to benefit others with their condition.

dashboard helps engage and empower patients and increases their confidence that they can manage and control their condition.¹⁴

Karin A, who has rheumatoid arthritis, says: "Nowadays I work together with my doctor and the computer for every change in my treatment. I can check my disease at home between visits. Before I go to see my doctor I report on and measure my own health. It's easy; I just click on the screen and enter how I feel now."

Clinical outcome measures seem to improve after patients start measuring, reporting, and sharing responsibility for the management of their condition with their physician. Patients in one region (Gävle County) that implemented routine use of PROMs in clinic visits had less disease activity, as measured by C reactive protein, than patients in regions where structured communication with doctors was not necessarily part of routine care.¹⁵

Patients have a personal identifier to access the registry, and the system is easy for patients to use and input information. The system also contains all the usual data used by medical staff to track outcomes (blood test results, inflamed joint counts, etc) so staff do not need to spend extra time inputting data or to move from one screen to another. Because patients track their outcomes between office visits and can communicate electronically when there is a change, the timing of appointments (urgent care for flare-up or routine follow-up) and their duration and content can be preplanned by the office staff and guided by patients' needs and priorities. Registry data can also be aggregated to examine population health, improve quality of care and provide transparent public reports on patient outcomes at the county level.

**US primary care model:
HowsYourHealth.org**

Developed in 1994 and disseminated on the internet since 1999 without charge to primary care practices, the HowsYourHealth system provides an immediate and standard source of information about patients' function, diagnosis, symptoms, health habits, preventive needs, capacity to self manage chronic conditions, and their experiences of care.¹⁶ Patients enter all the data themselves, mainly using tick boxes in response to questions. For practice improvement the system also provides a summary of all patient data (with national benchmarks) and a secure registry to target interventions at groups of patients with similar needs (such as those with diabetes, emotional problems, or low confidence to self manage health problems). The system is used by hundreds of practices in the United States and Canada, and initiatives to increase uptake are under way in Iowa, Massachusetts, and British Columbia. The system is endorsed by several medical specialty organisations.

Patients usually access HowsYourHealth from home or within the doctor's office. They have the opportunity to share their "check-up" data with the office staff, receive information tailored to their needs, and create a personal health plan for tracking and sharing their health status and behaviours. They can also access tools to help build confidence and skill in self management and better understand the risks and benefits of treatment. The system collects generic patient reported outcomes, including COOP/WONCA measures on pain, mobility, mental health, age and sex specific preventive health needs, and self management capacity for common risks and conditions. Patients control their HowsYourHealth information and its security, and it doesn't require a personal identifier or password.

A controlled trial involving 45 primary care physicians and 1651 patients aged ≥ 70 years found that the HowsYourHealth system significantly improved patient ratings of overall care quality and their understanding of important risks (such as falls and advance planning of care). Patients also reported that it helped with daily activities, emotional issues, and social support.⁷ Another controlled trial involving 47 primary care physicians and 644 adults with pain and emotional problems showed sustained improvement when HowsYourHealth was combined with a problem solving intervention supported by a nurse educator.⁸

Practices typically build HowsYourHealth into the routine “annual check-up,” and patients are usually happy to use it once they understand how it helps their care and improve the practice. James Bloomer, a family practitioner, describes his practice’s approach:

“Our practice routinely asks all patients to complete HowsYourHealth as part of their check-up. The tool often brings to light important concerns that we are unaware of, such as domestic abuse, and we spend no time actively collecting these data.”

Empirical observations from practices are used to expand knowledge about implementation and customisation. For example, experience has shown that using patient volunteers rather than practice staff to implement HowsYourHealth is often more successful.

Other examples of PROMs in practice

In England standard patient reported outcome measures are being used to track the outcomes of patients with four common surgical conditions.^{17 18} In the Netherlands, care teams are using web based applications and mobile health to monitor the quality of life of children with cancer.¹⁹ In the United States, over 60 practices in the ImproveCareNow network are using patient reported outcomes and clinical data to improve results for children with inflammatory bowel disease. Since establishing the network in 2007, remission rates have improved from 55% to 77% for 17 000 patients, in 30 states.²⁰

Looking to the future

Emerging information and communication technologies are spurring the development of new systems designed to capture and use the patient voice. However, the extent to which these systems can improve care will depend on how effectively clinicians respond to the patient voice.^{7 8} Future systems for incorporating the patient voice and patient reported outcomes into office practice need to be based on fundamental principles of patient centred care such as the timely explanation of information based on patient need and delivery of the information in a way that can help patients take effective actions to protect their health and wellbeing.

We are grateful for the contributions of James Bloomer, Angela Coulter, Dave deBronkart, Andy Gage, Sara Riggare, Rosemund Snow, Sven Tegmark, James Weinstein, Rupert Whitaker, and Paul Wicks.

Competing interests: We have read and understood BMJ policy on declaration of interests and declare ECN owns stock in Quality Data Management, JHW under licence with the Trustees of Dartmouth College develops HowsYourHealth.org and related websites and distributes them without compensation to primary care practices, and AH is a patient support system entrepreneur, patient advocate, and caregiver to a child with cystic fibrosis.
