Women’s health priorities and interventions

Building on the unfinished agenda, Marleen Temmerman and colleagues elaborate actions needed to improve the health and wellbeing of women and girls around the world.

Over the past decades, governments have taken steps towards improving women’s health in line with commitments made in key international summits. Progress has been made in reducing maternal mortality, which accelerated with the launch of the United Nations secretary general’s Global Strategy for Women’s and Children’s Health in 2010. Use of maternal healthcare and family planning has increased in some countries. Progress has also been seen on two determinants of women’s health—school enrolment rates for girls and political participation of women—but not for others such as gender based violence.

However, societies are still failing women in relation to health, especially in low resource settings. Discrimination on the basis of their sex leads to health disadvantages for women. Structural determinants of women’s health, along with legal and policy restrictions, often restrict women’s access to health services.

This paper elaborates the health problems women face, and priority interventions to overcome them, as a background for and informing the updating of the Global Strategy for Women’s, Children’s and Adolescents’ Health.

Methods
This paper is based on a desk review and synthesis of evidence drawing on global epidemiology and health estimates to identify gender differentials in mortality and morbidity. The interventions are based on syntheses of evidence drawn from evidence reviews previously conducted for WHO initiatives. We used three selection criteria to identify priority interventions. (1) Interventions that tackle major causes of morbidity and mortality in women and adolescent girls. (2) Interventions that have been shown to have a high impact on health and development of women and adolescent girls. (3) Interventions critical for the overall health and wellbeing of women, children, and adolescents (such as interventions related to harmful practices and violation of human rights).

This paper is based on a desk review and synthesis of evidence drawing on global epidemiology and health estimates to identify gender differentials in mortality and morbidity. The interventions are based on syntheses of evidence drawn from evidence reviews previously conducted for WHO initiatives. We used three selection criteria to identify priority interventions. (1) Interventions that tackle major causes of morbidity and mortality in women and adolescent girls. (2) Interventions that have been shown to have a high impact on health and development of women and adolescent girls. (3) Interventions critical for the overall health and wellbeing of women, children, and adolescents (such as interventions related to harmful practices and violation of human rights). We circulated a draft of the paper for comments through a web based consultation and finalised it according to comments received and expert feedback.

Unfinished agenda for women’s health
Poor sexual and reproductive health outcomes represent a third of the total global burden of disease for women aged 15-44 years. Unsafe sex and violence are major risk factors for death and disability among women and girls in low and middle income countries and continue to disproportionately affect marginalised groups in high income countries.

Although the global maternal mortality ratio—the number of maternal deaths per 100 000 live births—halved between 1990 and 2013, this progress is not sufficient to reach the target of millennium development goal 5 of a 75% reduction by 2015. In 2013 an estimated 289 000 women died from complications of pregnancy and childbirth; and 22 million unsafe abortions occurred in 2008 (half all induced abortions in that year), nearly all in low and middle income countries.

The burden of maternal morbidity, such as obstetric fistulas and uterine prolapse, continues to be high. Catastrophic and out of pocket health expenditure for healthcare services, such as treatment of complications resulting from unsafe abortion, continues to affect women and girls around the world. Each year, 5.4 million women endure pregnancies that end in stillbirth (2.6 million in 2009) or neonatal death (2.8 million in 2013). Worldwide, an estimated 225 million women have an unmet need for modern contraception.

In 2013 almost 60% of all new HIV infections among young people aged 15-24 years occurred in girls and young women. Tuberculosis is often linked to HIV infection and is among the leading causes of death in women of reproductive age (and among women aged 20-59 years) in low income countries.Nearly 30% of women and adolescent girls are affected by anaemia, leading to adverse effects on their overall health and wellbeing, especially during pregnancy and childbirth.

Sexually transmitted infections, of which human papillomavirus infection is the most common, disproportionately affect women and adolescent girls. About 70% of cases of cervical cancer worldwide are caused by human papillomavirus. Untreated syphilis is responsible for about for 21 000 stillbirths/early fetal deaths and about 92 000 neonatal deaths every year.

One in three women aged 15-49 years has experienced physical violence, sexual violence, or both by an intimate partner or sexual violence by a non-partner, with many short and long term consequences for their health. One in four girls and one in seven boys experience sexual violence before the age of 18.

Emerging priorities for women’s health
Shifts in population dynamics towards more ageing populations, along with an unprecedented growth in the world’s adolescent population, have led to greater complexities in the global burden of ill health, including an increase in non-communicable diseases (NCDs). In 2012 most premature deaths from NCDs among women aged 30-70 years (82% or 4.7 million) occurred in low and middle income countries, with higher rates in women aged 15-59 years than in high income countries.

Gender norms and societal structures mean that the mobility and physical activity of women and girls in some parts of the world is often restricted. This can be further compounded by factors related to income, household hierarchies, and roles. In some regions, this has an adverse effect on the health and wellbeing of women and girls. Furthermore, gestational diabetes affects about 15% of women worldwide.

Globally, tobacco use accounts for about 9% of all deaths due to NCDs in women.

KEY MESSAGES
Substantial progress has been made in the past two decades in improving maternal health, with a 45% reduction in maternal mortality, but much remains to be done. It is imperative to accelerate the momentum and protect the gains made for women’s health, as well as to tackle critical gaps and acknowledge the lessons learnt.

Key health systems interventions are needed to address structural determinants of women’s health, reduce inequities in access, improve quality of care, strengthen accountability, and promote adoption of innovations that improve performance.

Priority interventions for women’s health include providing health information and contraceptive services, strengthening maternal healthcare, tackling non-communicable diseases, and preventing and responding to violence against women and girls.
Maternal smoking is associated with risks in pregnancy, including ectopic pregnancy, preterm birth, placental problems, miscarriage, and stillbirth.23 Harmful use of alcohol, illicit drugs, and other psychoactive substances by girls and women, including during pregnancy, is increasing in many parts of the world. In 2012 an estimated 4% of deaths of women were attributable solely to alcohol use.24

Women’s cancers, especially breast and cervical cancer, result in high rates of mortality and morbidity, especially in low and middle income countries. Widespread major inequalities in access to early detection and screening lead to large variations in clinical outcomes and survival after treatment. Breast cancer, the leading cause of deaths from cancer in women (1.7 million new cases and 0.5 million deaths in 2012), is diagnosed in low and middle income countries mostly at advanced stages, when palliative care is the only option.25 Cervical cancer is the fourth most common cancer affecting women worldwide. In low and middle income countries, it is the third leading cause of death from cancer in women, and in most cases women have limited access to screening and treatment of pre-cancerous lesions, with resultant late stage identification.26

Mental disorders constitute another critical emerging health problem for women and girls. Suicide is a leading cause of death in adolescent girls and in women aged 20-59 years globally.27 Women experience more depression and anxiety than men.28 Patterns of mental health problems differ between men and women as a result of different gender roles and responsibilities, biological differences, and variations in social contexts.27 Women who have been exposed to violence by intimate partners are twice as likely to have depression and alcohol use disorders and four times more likely to commit suicide, compared with women not exposed to this violence.28 Mental health services are often limited in low income countries, and women benefit even less from these services than do men.27

Chronic obstructive pulmonary disease is also a leading cause of disease and death among older women. In low income countries, the primary risk factor for women’s ill health is exposure to indoor air pollution caused by the burning of solid fuels for heating and cooking. However, health systems are not adequately equipped to provide prevention and treatment of these conditions.

Globally, women represent a higher proportion of older adults. Traditionally, women have provided most of the care in the family, looking after both children and older people, often to the detriment of their own participation in the paid workforce. The consequences in older age include a greater risk of poverty, more limited access to good quality health-care and social care services, and poor health. Several serious medical conditions of older age, including dementia, are more common in women, yet women find it harder to access the treatment they need.

**Strengthening health systems and tackling structural determinants of women’s health**

Persistent obstacles in health systems to the realisation of women’s health and related human rights, including sexual and reproductive health and rights, include a lack of gender responsiveness, reflected by a lack of sex disaggregated data and gender analysis. This results in health services not taking into account the specific needs and determinants of women’s health or the effect on it of gender inequality. Removing these obstacles requires targeted innovations that tackle structural inequalities and improve the quality, coverage, and completeness of health services for women. Box 1 summarises health systems interventions for women’s health.

**Structural determinants of women’s health**

Sex based biological factors interact with inequalities based on gender, age, income, race, disability, ethnicity, class, and environmental factors among others in shaping women’s exposure to health risks, experience of ill health, access to health services, and health outcomes. Gender inequalities in the allocation of resources, such as income, education, healthcare, and nutrition, are strongly associated with poor health, requiring a multisectoral approach integrating the contribution of non-health sectors to the overall health and wellbeing of women and girls.

Creating an enabling legal and policy environment

Laws and policies have a direct bearing on the realisation of health and human rights by women and girls, including on sexual and reproductive health and rights. National and sub-national legal and policy frameworks should be aligned with recognised human rights norms and standards, and countries should establish or strengthen mechanisms to implement these standards.

Reducing inequalities

Another key focus in tackling the remaining gaps should be the persistent inequalities and inequities in the accessibility and quality of health systems across and within countries.28 In many settings, health systems continue to have limited accessibility for certain populations, such as for poor people, older people, adolescents, rural residents, and residents of urban slums, and for uninsured or undocumented people,29 as well as limited capacity as measured by indicators such as health worker density, coverage of critical services, use of health information systems, availability of essential medicines and supplies, and quality assurance.29

---

**BOX 1: HEALTH SYSTEMS INTERVENTIONS FOR WOMEN’S HEALTH**

- Universal health coverage for key health interventions for women
- Inequities in access
  - Steps to enhance coverage (physical, social, geographic, linguistic, financial)
  - Removal of barriers to access, including legal and policy barriers, criminalisation, third party authorisation, and overly broad conscientious objection
- Quality of care, including supplies
  - Quality assurance of service delivery, update of evidence based norms, standards, and policies
  - Adequate supplies for key women’s health problems
  - Respectful care standards and cultural sensitivity
- Health workforce
  - Development and distribution of health workforce for women’s health problems, including midwives
  - Pre-service and in-service training
  - Provision of incentives to enhance quality, retention, etc.
- Monitoring and accountability
  - Investing in strengthening the overall governance of the health system to ensure better accountability for results and for realisation of rights
  - Strengthening management capacity at national and sub-national levels
- Adoption and institutionalisation of innovations that enhance quality, coverage, efficiency, and/or completeness of health interventions to women
  - Client specific innovations that improve access and reduce barriers, including the use of digital technologies
  - Health system innovations that improve performance and drive measurement and accountability, including digital innovations for vital events
Quality of care
Women’s health services, particularly sexual and reproductive health services, are often not provided at a level of quality that meets human rights standards. The persistence of poor sexual and reproductive health outcomes despite availability of supplies and facilities underscores the need to strengthen the quality of health systems. According to the recent WHO multi-country survey on maternal and newborn health, even when the coverage of effective interventions is high (above 80%) many women still die or experience severe morbidity from haemorrhage, hypertensive and other disorders of pregnancy, and prolonged obstructed labour (often resulting in death, stillbirth, or obstetric fistulas).

Quality of care must therefore go side by side with the increase of service coverage, as this alone does not guarantee the health results. Strengthening health networks, transportation, and referral systems is still an unfinished agenda in many countries. Upgrading of first and second level facilities with appropriate infrastructure and equipment, and providing adequate numbers of skilled and motivated health workers, with ongoing training and mentoring for women’s health, including on sexual and reproductive health and abortion care, and on tackling violence against women, is necessary to increase coverage and facilitate access.

Quality of care is a multidimensional concept that is affected by stakeholders’ priorities and context. Attributes of quality of care include access to care, effectiveness of care, safety, equity, communication, acceptability, efficiency, and privacy and confidentiality.

Enhancing accountability
The Commission on Information and Accountability for Women’s and Children’s Health emphasised multiple dimensions of accountability, by adopting a framework built on three pillars: monitoring, review, and action (including redress). The independent Expert Review Group, established to monitor and assess progress in implementation of recommendations made by the commission, has stated that accountability needs to be based on certain core principles: clarity about stakeholders’ responsibility for action; accurate measurement; independent verification; impartial, transparent, and participatory review; and clear recommendations for future action.

Accountability is also intrinsic to ensuring that individuals’ agency and choice are respected, protected, and fulfilled. Agency and choice are fundamental to enabling people to have a voice and to hold governments and all relevant stakeholders to account.

Promotion and protection of the international development agenda requires placing the human rights and health of women and adolescent girls, particularly sexual and reproductive health and rights, at its centre. Participatory monitoring and accountability mechanisms that meaningfully engage women at the sub-national, national, and global levels are a critical part of this.

Priority interventions for women’s health
On the basis of the existing evidence and reviews conducted, we propose several priority interventions. Box 2 gives a synthesis of these interventions, which are not in an order of priority.

Providing health information and comprehensive sexuality education
Evidence based health information and comprehensive sexuality education (CSE) is a key intervention for promotion and protection of women’s health. Such education and information should be available to all adolescents and youths, in and out of school, as well as to adult women. CSE provides thorough, scientifically accurate, non-judgmental information and assists people to develop skills for decision making, critical thinking, communication, and negotiation of interpersonal relationships. Quality CSE programmes cover human rights, gender equality, respectful relationships, human sexuality, and sexual and reproductive health and rights. Effective CSE programmes seek to roll out nationwide curriculums and teacher training materials based on interactive methodologies; they select and supervise teachers and facilitators; and they work with parents, school principals, and programme managers, among others, at community level and through meaningful participation of adolescents. Specific attention needs to be paid to adolescent girls in the context of CSE programmes.

Contraceptive information and services for all who need them
Information on contraception and integrated comprehensive sexual and reproductive health services are vital means for women and girls to maintain health, and their availability is necessary for women and girls to enjoy their human rights. Contraception has clear health benefits. For example, prevention of unintended pregnancies results in a subsequent decrease in maternal and infant mortality and morbidity. Providing access for all women in developing countries who have an unmet need for modern methods of contraception would prevent 54 million unintended pregnancies, 26 million abortions (of which 16 million would be unsafe), and 7 million miscarriages; this would also prevent 79 000 maternal deaths and 1.1 million infant deaths. This situation would particularly benefit adolescent girls, who are at increased risk for medical complications associated with pregnancy and who are often forced to make compromises in education and employment that may lead to poverty and lower educational attainment.

Effective policies at the national and local levels should ensure availability of a mix of accessible, acceptable, and high quality modern contraceptive methods, including emergency contraception, to meet women’s needs across the life course; these should be evidence based and free from bias, discrimination, and unnecessary medical eligibility criteria. Financing for family planning should be strengthened through costed implementation plans, health finance facilities, and national budgets. Providers should be trained and supervised to meet human rights standards for quality care.
Strengthening maternal healthcare
As maternal and child mortality continues to decrease sharply in many countries, to make more progress, priority attention is needed to ensure the quality of maternal healthcare. Functioning health systems will include emergency obstetric and newborn care and strong capacity at the secondary level to treat complications of childbirth, with effective referral from the community and primary levels.37 38 Further strengthening of health services delivery systems is also needed, taking into account task shifting and innovative approaches such as mHealth and eHealth.

Strengthening the health workforce
Attention is needed to educate, deploy, retain, and improve the quality of the cadres of primary healthcare workers, such as midwives and nurses, through quality education, effective regulation, and an enabling work environment that includes effective referral.39 Healthcare workers should be empowered and provided with the necessary knowledge, skills, medicines, and equipment. Furthermore, health workers should be provided with training and capacity building to sensitise them to approach the health needs of women and adolescent girls in a more responsive manner.

Providing safe abortion and post-abortion care
Unsafe abortion, one of the leading causes of maternal death and injuries, is entirely preventable because technologies and safe procedures are well known, cost little, and should be widely available. WHO’s technical and policy guidelines for access to safe abortion should be implemented.40 Laws restricting access to safe abortion do not reduce or end recourse to abortion, and abortion related mortality is higher in countries with restrictive laws. The UN Special Rapporteur on the Right to Health has found that criminalising reproductive behaviours, including abortion, is a violation of human rights and contributes to poor health outcomes.41 Although access to post-abortion care for treatment of the complications of unsafe abortion has increased, women in many countries still do not have access to this life saving care or are mistreated when they seek it.

Preventing and responding to violence against women and girls
Challenging social norms and gender inequalities is a critical element in preventing and responding to all forms of violence against women and girls. This requires multi-sector programmes and strategies that address structural determinants, including gender equality and the empowerment of women. Laws, policies, protocols, and guidelines are needed for all sectors, emphasising that violence against women and girls is a violation of human rights, imposes enormous health burdens on individuals, families, and society, and will not be tolerated. The health system has an important role in the prevention of and response to violence against women and girls by ensuring access to timely, effective, and affordable health services for women and girls who are victims of violence, particularly sexual and reproductive health services. Sexual and reproductive health, adolescent health, and maternal health services offer unique entry points to identifying violence and providing the necessary support and care to women and girls exposed to violence, including mental health, emergency contraception, safe abortion, and STI and HIV prophylaxis for post-rape care, in line with WHO’s clinical and policy guidelines. This requires providers to be adequately trained and supported.

Tackling non-communicable diseases
As detailed above, women are increasingly facing a disproportionate burden of NCDs. Prevention requires interventions to promote healthy behaviours and reduce risk factors for NCDs, and governments need to take steps to overcome economic, socio-cultural health inequalities and geographic barriers. Providing women with clean cooking and heating devices reduces their risk for several NCDs while also protecting the health of infants and young children. Interventions include integration of prevention and control of NCDs into existing health systems initiatives; protection of women and girls from aggressive marketing of tobacco products through accelerated and effective implementation of the Framework Convention on Tobacco Control; inter-sectoral collaboration to identify and promote actions outside health systems in relation to NCDs; greater involvement of women and girls in identifying problems and solutions and implementing policies in the fight against NCDs; integration of sex and gender in the design, analysis, and interpretation of studies on NCDs by research institutions; and innovative partnerships to improve access to affordable, high quality, essential medicines to treat NCDs.42

Adequate nutrition
Iron deficiency anaemia increases the risk of haemorrhage and sepsis during childbirth. It causes cognitive and physical deficits in young children and reduces productivity in adults. Women and girls are most vulnerable to anaemia owing to insufficient iron in their diets, menstrual blood loss, and periods of rapid growth. In some regions, women and girls are denied access to nutrition owing to cultural factors and societal norms. This severely affects the overall health and wellbeing of women and girls, especially during pregnancy, and leads to severe birth outcomes and health conditions. This requires cross sectoral collaboration to ensure provision of adequate nutrition to women and girls. For example, the paper by Branca and colleagues recommends that interventions to reduce iron deficiency anaemia need to be rolled out at a larger scale, achieving universal coverage.43 This also requires interventions to ensure gender equality and promotion of women’s empowerment to ensure women’s health and wellbeing.
full access to and control over resources and social protection.

**Mental health**

Gender is a critical determinant of mental health and mental illness. The morbidity associated with mental illness has received substantially more attention than the gender specific determinants and mechanisms that promote and protect mental health and foster resilience to stress and adversity. Gender differences occur particularly in the rates of common mental disorders such as depression, anxiety, and somatic complaints. These disorders affect approximately one in three people in the community (with a female predominance), are closely associated with intimate partner violence, and constitute a serious public health problem. Reducing gender disparities in mental health requires action at many levels. In particular, national mental health policies must be developed on the basis of an explicit analysis of gender disparities in risk and outcome. This further requires investments in gender-sensitive treatment approaches and services to be developed at the national level.44 For women to be able to access treatment at all levels from primary to specialist care and inpatient as well as outpatient facilities, services must be tailored to meet their needs.44 Women must therefore have access to meaningful assistance to seek treatment, and the full range of women’s psychosocial and mental health needs must be addressed. This, according to WHO, involves services adopting a life course approach, by acknowledging current and past gender specific exposures to stressors and risks and by responding sensitively to life circumstances and ongoing gender based roles and responsibilities.44

**Conclusion**

Despite progress, persisting and emerging problems challenge women’s health. Responding to these requires a comprehensive approach including implementation of effective interventions at both clinical and health systems level. Additionally, environmental, social, economic, and political determinants that result in unequal access to care should be tackled to ensure the ending of preventable deaths, morbidities, and disabilities among women and improve their health. A focus on inequalities and on marginalised groups, including in humanitarian settings, will help in achieving convergence between high and low income countries within a generation.
