3  
4 **Abstract:**

5  
6 **Objective:** To study the clinical characteristics of the imported 2019-novel coronavirus  
7  
8 patients in Zhejiang Province.

9  
10  
11 **Design:** Multicenter, retrospective, observational study

12  
13  
14 **Setting:** The study covering eight hospitals which located in the different part of Zhejiang  
15  
16 province.

17  
18  
19 **Participants:** Since January 2020, we collected data of 62 patients with laboratory-confirmed  
20  
21 2019-nCoV in designated hospitals of Zhejiang province.

22  
23  
24 **Main outcome measures:** We used a standardized case-report form to collect clinical data. If  
25  
26 information was not clear, the working group in Hangzhou contacted the physician  
27  
28 responsible for the treatment of the patient for clarification.

29  
30  
31 **Results:** Of the 62 patients studied, only one patient was admitted to the intensive care unit  
32  
33 (ICU), no patient died until the submission time. According to our research, none of the  
34  
35 infection cases in Zhejiang had ever been exposed to the Huanan seafood marker, all the  
36  
37 patients were infected by human transmission. The most common symptoms at onset of  
38  
39 illness were fever (48 [77.4 %]), cough (50 [80.6%]), expectoration (35 [56.5%]), headache  
40  
41 (21 [33.9%]), myalgia or fatigue (32 [51.6%]), diarrhoea (3 [8.1%]), and hemoptysis (2  
42  
43 [3.2%]). Rare of patients (2 [3.2%]) developed shortness of breath. The median time from  
44  
45 exposure to infections to illness onset was 4 days (IQR: 3-5 days), from onset of symptoms to  
46  
47 first hospital admission was 2 days (IQR: 1-4.3 days).

48  
49  
50 **Conclusions:** The 2019-nCoV could be easily transmitted from human to human. At present,  
51  
52 the symptoms of secondary infection patients are relatively mild.  
53

## 68 **Introduction**

69 In December, 2019, a group of patients with pneumonia of unknown reason were confirmed  
70 to be infected with 2019 novel coronavirus (2019-nCoV) in Wuhan, Hubei, China, which had  
71 not been detected in humans and animals before.<sup>1</sup> Epidemiological evidence suggested that  
72 most of those patients had been presented in a local seafood market in Wuhan<sup>2</sup> and the virus  
73 gene sequence of patients was highly similar to that of bats and snakes.<sup>3,4</sup> The viral  
74 2019-nCoV was a kind of coronavirus that was very similar to the severe acute respiratory  
75 syndrome coronavirus (SARS-CoV) and Middle East respiratory syndrome coronavirus  
76 (MERS-CoV) which had caused more than 10000 cases and 1632 deaths across the globe.<sup>5-7</sup>  
77 Some researchers found that the 2019-nCoV has good affinity to human respiratory receptor,<sup>8</sup>  
78 which indicated that 2019-nCoV may have the potential to pose a global public health threat.

79 At the beginning, nearly all of the patients were related to the Huanan seafood market  
80 and the cases were concentrated in Wuhan.<sup>9</sup> Global attention was soon attracted on the  
81 situation because of the increasing number of new cases.<sup>2</sup> The new type of coronavirus  
82 infection is mainly transmitted from animals to humans, and by January 2020, the main  
83 infection cases was suspected to be transmitted from human to human.<sup>10</sup> Since January 2020,  
84 the spread of 2019-nCoV starts to escalate at an alarming rate and the virus quickly expand to  
85 most parts of China and even other countries. Up to 25 January 2020, there were a total of  
86 1320 confirmed cases, including 1297 cases from China and 23 oversea cases from 9  
87 countries.<sup>11</sup> These figures update every day and are expected to increase in the further.

88 Despite the increasing number of confirmed cases, the clinical investigation of patients  
89 was still limited in the literature. A previous study has reported the clinical characteristics of

1  
2  
3  
4 90 initial 41 patients in Wuhan area, which contributes to our epidemiological, clinical,  
5  
6 91 laboratory, and radiological characteristics and treatment and clinical outcomes of those  
7  
8  
9 92 initial patients.<sup>9</sup> Another study conducted by Chan et al. revealed a familial cluster of  
10  
11 93 2019-nCoV and clearly suggested person-to-person transmission in family homes or hospital,  
12  
13  
14 94 and intercity spread of this novel coronavirus are possible.<sup>10</sup> At present, as large number of  
15  
16  
17 95 people were returning home from Wuhan during the Chinese Lunar New Year travel rush,  
18  
19  
20 96 more second-generation or later-generations cases are expected to emerge all over the country  
21  
22 97 and even all over the world. We found that the characteristics of the imported patients were  
23  
24  
25 98 different from those initial patients in Wuhan reported by Bin Cao.<sup>10</sup> It is very important to  
26  
27 99 study the clinical characteristics of the imported patients in Zhejiang Province.

30 100 Through the analysis of the characteristics of these people, we aim to provide the  
31  
32 101 experiences for prevention and treatment of new coronavirus infection all over the country  
33  
34  
35 102 and abroad. In this article, we described clinical characteristics and laboratory abnormalities  
36  
37  
38 103 in 62 cases of second generation patients infected with 2019 novel coronavirus in Zhejiang,  
39  
40 104 China.

## 45 106 **Method**

### 48 107 **Data sources**

50 108 We conducted a retrospective study focusing on the clinical characteristics of confirmed  
51  
52  
53 109 cases of the 2019-nCoV infection in Zhejiang Province. All suspected cases with fever and  
54  
55  
56 110 dry cough, especial those with travel history to Wuhan or history of exposure to infected  
57  
58  
59 111 person within 2 weeks before the onset of illness, were transferred to designated hospitals  
60

1  
2  
3  
4 112 since January, 2020. The case definitions of confirmed human infection with the 2019-nCoV  
5  
6 113 have been described by Zhu et al.<sup>1</sup> Only patients with laboratory-confirmed infection were  
7  
8  
9 114 enrolled in this study.  
10

11  
12 115 The medical records of patients were extracted and sent to the data-collection center in  
13  
14 116 Hangzhou. A team of physicians who had been taking care of patients with 2019-nCoV  
15  
16  
17 117 infection collected and reviewed the data. This study was approved by the Ethics Committee  
18  
19 118 of the First Affiliated Hospital, Zhejiang University School of Medicine. Because of the  
20  
21  
22 119 urgent need to collect data on this emerging pathogen, the requirement for informed consent  
23  
24  
25 120 was waived. We used a standardized case-report form to collect clinical data. If information  
26  
27 121 was not clear, the working group in Hangzhou contacted the physician responsible for the  
28  
29  
30 122 treatment of the patient for clarification.  
31

32  
33 123

#### 34 35 124 **Laboratory confirmation and treatment**

36  
37  
38 125 Laboratory confirmation of the 2019-nCoV was performed with real-time PCR described by  
39  
40 126 Huang et al.<sup>9</sup> The virus detection was repeated for two times with 24 hours apart.  
41

42  
43 127 . Basic tests were conducted including complete blood count, serum biochemical test and  
44  
45 128 so on. Most of patients received anti-virus treatment including interferon beta-1b inhalation  
46  
47  
48 129 (5MU/bid) or Lopina veletonavir (400mg/100mg bid). When the resting respiratory rate of  
49  
50  
51 130 patient is more than 30 times per minute at rest, or the oxygen saturation of the patient is  
52  
53 131 below 93% without oxygen, or the multiple pulmonary lobes of patients were involved with  
54  
55  
56 132 more than 50% progress in 48 hours, the corticosteroid therapy and gamma globulin therapy  
57  
58 133 were given to the patients. The probiotics therapy was performed in most cases. Antibiotics  
59  
60

1  
2  
3  
4 134 (oral and intravenous) were administered if the fever lasted longer than 7 days or CRP  $\geq$  30.  
5  
6 135 Suspected patients have no access to hospital discharge or discontinuation of isolation until  
7  
8  
9 136 2019-nCoV clearance.  
10

11 137

## 14 138 **Statistical analysis**

16  
17 139 Since Huang et al.<sup>9</sup> have shown that patients would get worse on the 10<sup>th</sup> day after onset, we  
18  
19 140 compared the whole cohort with the ones with the course of longer than 10 days. Continuous  
20  
21  
22 141 variables were summarized as either means and standard deviations or medians with  
23  
24 142 interquartile ranges. For categorical variables, the percentages of patients in each category  
25  
26  
27 143 were calculated. All analyses were done with SPSS software, version 22.0  
28  
29

30 144

## 32 145 **Results**

### 35 146 **Epidemiologic characteristics**

37  
38 147 By Jan 23, 2020, the clinical data of 62 patients identified as laboratory-confirmed  
39  
40 148 2019-nCoV infection were collected in Zhejiang. Twenty-five (40.3%) of the  
41  
42  
43 149 2019-nCoV-infected patients were aged 19-40 years, and 33 (53.2%) were aged 41-65 years,  
44  
45 150 2 (3.2%) were children and 2 (3.2%) were elderly. The median age of the patients was 41  
46  
47  
48 151 years (IQR 32–52; table 1). In our cohort of the 62 patients as of January 23, more than half  
49  
50  
51 152 of the infected patients were men (36 [58.1%]); no patients had a history of Huanan seafood  
52  
53  
54 153 market exposure, all patients (62/62) had exposure to confirmed 2019-nCoV infected patients.  
55  
56 154 Among 62 patients, 23(37.1%) patients had long term residence in Wuhan. Other 39(62.9%)  
57  
58 155 patients had short term trip to Wuhan before onset. These patients who had short term trip to  
59  
60

1  
2  
3  
4 156 Wuhan were concluded to calculate the incubation period. At the same time, we selected the  
5  
6  
7 157 patients (n=33) with course longer than 10 days. Among these patients, 10 (30.3%) of the  
8  
9 158 2019-nCoV-infected patients were aged 19-40 years, and 22 (66.7%) were aged 41-65 years,  
10  
11  
12 159 and 1 (3%) were elderly. The median age of the patients was 45 years (IQR 37–54.5; table 1).  
13  
14  
15  
16

### 161 **Clinical features**

162 Among the group of 62 patients, one third of patients had underlying diseases (20 [32.3%]),  
163 including liver disease (7 [11.3%]), hypertension (5 [8.1%]), chronic obstructive pulmonary  
164 disease diabetes (1 [1.6%]), renal diseases (1 [1.6%]) and cardiovascular disease (1 [1.6%]).  
165 More than one third were found to be associated with familial clusters (21 [33.9%]). At the  
166 same time, we selected the patients (n=33) with course longer than 10 days. More than one  
167 third patients had underlying diseases (13 [39.4%]), including liver disease (4 [12.1%]),  
168 hypertension (4 [12.1%]), chronic obstructive pulmonary disease diabetes (1 [3%]), and  
169 cardiovascular disease (1 [1.6%]). Less than one third were found to be associated with  
170 familial clusters (21 [33.9%]).

171 Among the group of 62 patients, we found that the median time of incubation period  
172 from exposure was 4 days (IQR 3-5). The median time from onset of symptoms to first  
173 hospital admission was 2 days (IQR 1-4.3). The most common symptoms at onset of illness  
174 were fever (48 [77.4 %]), cough (50 [80.6%]), expectoration (35 [56.5%]), headache (21  
175 [33.9%]), myalgia or fatigue (32 [51.6%]), diarrhoea (3 [8.1%]), and hemoptysis (2 [3.2%]).  
176 Only 2 patients (2 [3.2%]) developed shortness of breath. Among those patients who have  
177 disease course over 10 days. We found that the median time of incubation period from  
178

1  
2  
3  
4 178 exposure was 3 days (IQR 3-4). The median time from onset of symptoms to first hospital  
5  
6 179 admission was 6.5 days (IQR 5.0-9.0). The most common symptoms at onset of illness were  
7  
8  
9 180 cough (27 [81.8 %]), fever (26 [78.8%]), expectoration (19 [57.6%]), myalgia or fatigue (19  
10  
11 [57.6%]) , headache (15 [45.5%]), diarrhea (3 [9.1%]), and hemoptysis (2 [6.1%]). Only 1  
12  
13  
14 182 patient (1 [3.0%]) developed shortness of breath.

15  
16  
17 183 On admission, among the group of 62 patients, the blood counts of patients showed  
18  
19 184 leucopenia (white blood cell count less than  $4 \times 10^9/L$ ; 19 [30.6%]) and lymphopenia  
20  
21 (lymphocyte count  $<1.0 \times 10^9/L$ ; 26 [41.9%]; table 2). The D-dimer level were higher  
22  
23 185 (median D-dimer level 0.2 mg/L [IQR 0.2-0.5]). Levels of aspartate aminotransferase  
24  
25 186 (median D-dimer level 0.2 mg/L [IQR 0.2-0.5]). Levels of aspartate aminotransferase  
26  
27 187 increased in 10 patients (16.1%). Most patients had normal serum levels of procalcitonin  
28  
29 (procalcitonin  $<0.1$  ng/mL; 55 [88.7%] patients). Abnormalities in chest CT images or X ray  
30  
31 188 were detected among all patients. Of the 62 patients, 52 (83.9%) had bilateral involvement  
32  
33 189 (table 2). The typical findings of chest CT images of infection patients on admission were  
34  
35 190 bilateral or multiple lobular or subsegmental areas of consolidation or bilateral ground-glass  
36  
37 191 opacity (Figure 1). Only 1 patient didn't have pneumonia. Among the 62 patients, only 1  
38  
39 192 patient transferred to intensive care unit for acute respiratory distress syndrome and received  
40  
41 193 mechanical ventilation (Table 3). Of all the patients, 88.7% (55/62) received antiviral therapy,  
42  
43 194 45.2% (28/62) were administered with empirical antibiotic treatment. Besides, 25.8% (16/62)  
44  
45 195 patients were given systematic corticosteroids and gamma globulin therapy. One (1.6%)  
46  
47 196 patients have been discharged and no patients died up to now. Fitness for discharge was  
48  
49 197 based on abatement of fever for at least 3 days, with improvement of chest radiographic  
50  
51 198 evidence and viral clearance in respiratory samples from lower respiratory tract.

4 2005  
6 201 **Discussion**

7  
8  
9 202 As of January 27, 2020, more than 2000 laboratory-confirmed 2019-nCoV infections were  
10  
11 203 reported in China.<sup>12</sup> The number of infections is increasing quickly. It is possible that a larger  
12  
13  
14 204 number of patients with infections were not diagnosed because their symptoms were less  
15  
16  
17 205 severe and the infection has a period of incubation. Thousands of suspected patients might be  
18  
19  
20 206 diagnosed in the next few days. The clinical features of 2019-nCoV cases in Wuhan were not  
21  
22  
23 207 same as that in other areas in China. According to our data, none of the infection cases in  
24  
25 208 Zhejiang had ever been exposed to the Huanan seafood market, all the patients were infected  
26  
27  
28 209 by human transmission. In addition, there are a large part of family clusters in Zhejiang  
29  
30 210 infected cases, which is consistent with Professor Yuan's article and more effectively proves  
31  
32  
33 211 the view of human to human transmission.<sup>10</sup> This would stress on the importance of air  
34  
35 212 prevention.

36  
37  
38 213 The large part of Zhejiang patients were male patients, but the age range is larger, as  
39  
40 214 the 2019-nCoV also infected children and the elderly.<sup>9</sup> There is not much difference between  
41  
42  
43 215 the initial clinical symptoms of the Zhejiang cases and those in Wuhan. But most of the  
44  
45  
46 216 patients in Zhejiang Province are of mild to moderate symptoms, and only a small part of  
47  
48  
49 217 them have dyspnea. Only one patient developed to acute respiratory distress syndrome and  
50  
51 218 admitted to the ICU. From the laboratory test indicators, the illness of the second-generation  
52  
53  
54 219 of patients are also mild. In particular, there were less patients with abnormal renal function,  
55  
56 220 lactate dehydrogenase and procalcitonin. Through media and national advocacy, the patients  
57  
58  
59 221 with fever, cough, expectoration and other upper respiratory symptoms were asked to go to  
60

1  
2  
3  
4 222 hospital at an earlier stage. Even those with the contact with other patients or suspected  
5  
6 223 patients were asked to go to hospital. We selected some patients with a course of more than  
7  
8  
9 224 10 days for analysis. However, after comparing the clinical features of our patient (with  
10  
11 225 course longer than 10 days) with Wuhan patients, we found that the secondary-generation  
12  
13  
14 226 cases in Zhejiang Province are less severe than the primary cases in Wuhan<sup>9</sup> (Table 4). This  
15  
16  
17 227 phenomenon had also appeared in during the transmission of MERS-CoV. The global case  
18  
19 228 mortality of MERS-CoV was about 40%, while the mortality of second generation of  
20  
21  
22 229 MERS-CoV was about 20%.<sup>13,14</sup>

23  
24  
25 230 There was not much differences in the antivirus therapy between Zhejiang and Wuhan.  
26  
27 231 However, the antibiotic treatment usage rate and corticosteroid usage rate were different.  
28  
29  
30 232 Less than half patients received antibiotic therapy in Zhejiang Province. Whether the use of  
31  
32 233 antibiotics and steroids affects the prognosis of patients remains unknown. Till now, we have  
33  
34  
35 234 no death patient in Zhejiang province and one patient has recovered after 7 days of treatment  
36  
37  
38 235 in hospital.

39  
40 236 Given that most infections in Zhejiang were secondary-generation infections, our  
41  
42 237 finding will provide valuable information to understand the clinical features of the  
43  
44  
45 238 increasingly second-generation and later-generation patients. The clinical characteristics of  
46  
47  
48 239 our study population can represent most of the patient's infection since January 2020. Many  
49  
50  
51 240 proposals should be administrated by the government, such as sealing off the city from all  
52  
53  
54 241 outside contact of Wuhan; forbidding gathering of more than 100 persons; efficient daily  
55  
56 242 public education of 2019-nCoV precaution; encouraging people to cancel the traditional  
57  
58  
59 243 family gathering during Chinese Lunar New Year and extending the New Year holiday to  
60

1  
2  
3  
4 244 prevent large-scale spreading.  
5

6 245 Our study has several limitations. Firstly, there are only 62 cases were included in our  
7  
8  
9 246 study. During the period of data collection, a large number of patients showed up So we just  
10  
11 247 collected most but not all of the patients with laboratory confirmed illness in Zhejiang  
12  
13  
14 248 Province in that time. Secondly, the patients were only from Zhejiang province which may  
15  
16  
17 249 not be able to fully reveal the clinical features of secondary infection patients. Thirdly, at the  
18  
19  
20 250 time of submission of the manuscript, most patients were still not discharged, so we were  
21  
22 251 unable to estimate either the case fatality rate or predictors of fatality. Moreover, the course  
23  
24  
25 252 of some of our patients may be shorter than 10 days of observation period, which may cause  
26  
27 253 the bias of clinical observation characteristics.  
28  
29

30 254 In conclusion, 2019-nCoV was easily transmitted from human to human At present, the  
31  
32 255 symptoms of secondary-generation patients are relatively mild. At present, there is no  
33  
34  
35 256 effective drug treatment and vaccine. It is still necessary to strengthen virus monitoring in  
36  
37  
38 257 time and to develop drugs and vaccines for 2019-nCoV as soon as possible.  
39
