ABSTRACT (249 words)**Objective**

As large-scale immunization programs against COVID-19 proceed around the world, safety signals will emerge that need rapid evaluation. We quantified the population-based, age- and sex-specific background incidence rates of potential adverse events of special interest (AESI) in eight countries.

Design

Multi-national network observational retrospective cohort study.

Setting

Electronic medical records and administrative claims data from Australia, France, Germany, Japan, Netherlands, Spain, United Kingdom, and the United States, mapped to a common data model.

Participants

126,661,070 individuals observed for at least 365 days before 1 January 2017, 2018, or 2019 from 13 databases.

Main outcome measures

Incidence rates of AESIs (acute myocardial infarction, anaphylaxis, appendicitis, Bell's palsy, deep vein thrombosis, disseminated intravascular coagulation, encephalomyelitis, Guillain-Barre syndrome, hemorrhagic and non-hemorrhagic stroke, immune thrombocytopenia, myocarditis/pericarditis, narcolepsy, pulmonary embolism, and transverse myelitis) stratified by age, sex, and database. We also pooled rates across databases using random effects meta-analyses.

Results

The background incidence rates varied greatly between databases and by age and sex. Some AESI (e.g., myocardial infarction) increased with age, while others (e.g., anaphylaxis) were more common in young people. AESI were therefore classified differently according to age. For example, myocardial infarction was very rare in children, rare in women aged 35-54 years, uncommon in men and women aged 55-84 years, and common in those aged ≥ 85 years.

Conclusions

We report robust baseline rates of prioritised AESI across 13 databases. Age, sex, and variation between databases should be considered if background AESI rates are compared to event rates observed with COVID-19 vaccines.

SUMMARY BOX

What is already known on this topic

- Background rates of adverse events of special interest (AESI) have historically played an important role in monitoring vaccine safety.
- Most studies to date have focused on single or very few events, applied different study designs, and no publication specifically focused on COVID-19 vaccine prioritised AESI.
- No international transcontinental study on background rates on COVID-19 vaccine AESI using the same study design have been reported.

What this study adds

- In this multi-national network cohort study, we comprehensively assessed the background incidence rates of 15 AESI using observational data from Australia, France, Germany, Japan, Netherlands, Spain, the United Kingdom (UK), and the United States (US).
- We found considerable heterogeneity between geographies and databases, calling for caution in the interpretation of any differences between observed and expected rates.
- We also observed considerable variability in observable rates of AESI between age groups and sex, demonstrating the need for standardization if background rates are used for surveillance purposes.

MAIN TEXT (2966 words)**INTRODUCTION**

On 11 March 2020, the World Health Organization (WHO) declared the outbreak of COVID-19, caused by the SARS-CoV-2 virus, a global pandemic. As of March 2021, over 100 million confirmed cases and 2.7 million deaths have been reported worldwide.[1] Vaccines for COVID-19 have been developed at unprecedented speed, with phase 3 clinical efficacy trials reporting results for some vaccines less than a year after the WHO declared the pandemic. Several vaccines have been authorised by regulators since December 2020, such as the European Medicines Agency (EMA), the Food and Drug Administration (FDA) in the US, and the UK Medicines and Healthcare Products Regulatory Agency (MHRA). Large-scale immunization programs are ongoing worldwide.

While this scientific achievement should be celebrated, we must recognize that emergency use is accompanied by residual uncertainty about the safety and effectiveness of vaccines in all populations of interest. As with all medical products reaching the milestone of regulatory authorization, vaccine safety must continue to be monitored to complement what was initially learned during clinical development. Spontaneous adverse event reporting has served as a foundational component of post-approval pharmacovigilance activities to ensure the safe and appropriate use of medical products. Observational healthcare data captured during the routine course of clinical care, such as electronic health records and administrative claims, can augment pharmacovigilance by providing real-world context about potential adverse events and their rates in populations of interest. Background rates of adverse events have historically played an important role in monitoring the safety of vaccines by serving as a baseline comparator for observed rates among those vaccinated.[2,3] Each new vaccine has potential adverse events of special interest (AESI) that warrant focused evaluation, based on historical precedent set by prior vaccines and knowledge acquired during its development.

As COVID-19 vaccines have received authorization for emergency use, regulatory agencies around the world have been preparing safety surveillance strategies. The US FDA Center for Biologics Evaluation and Research published a protocol on “Background Rates of Adverse Events of Special Interest for COVID-19 Vaccine Safety Monitoring.”[4] The European Medicines Agency-funded vACCine covid-19 monitoring readinESS (ACCESS) project also included estimation of background AESI rates in their protocol.[5] Recognizing the global burden that COVID-19 represents and following the WHO Council for International Organizations of Medical Sciences (CIOMS) guidance that the most valid data for comparison in a particular area are the background rates from the local population,[6] the Observational Health Data Sciences and Informatics (OHDSI) community collaborated to design and execute an international open science study to characterize background rates of COVID-19 AESI. In this paper, we provide descriptive epidemiology context for COVID-19 AESIs using observational data from Australia, France, Germany, Japan, Netherlands, Spain, the UK, and the US.

METHODS**Study design**

A multinational, multi-database population-based network cohort study.

Data sources

We included thirteen databases from eight countries, of which eight were electronic health record data sources and five were administrative claims data sources.

The electronic health record databases were: 1. IQVIA Australia Electronic Medical Records (IQVIA_AUSTRALIA); 2. Integrated Primary Care Information (IPCI_NETHERLANDS), a primary care records database from the Netherlands; 3. IQVIA Longitudinal Patient Data France (IQVIA_FRANCE); 4. IQVIA Disease Analyser Germany (IQVIA_GERMANY); 5. Information System for Research in Primary Care (SIDIAP_H_SPAIN), a primary care records database that covers over 80% of the population of Catalonia, Spain; 6. Clinical Practice Research Datalink, which consists of data collected from UK primary care for all ages (CPRD_GOLD_UK); 7. Columbia University Irving Medical Center (CUMC_US), which covers the New York-Presbyterian Hospital/Columbia University Irving Medical Center in the US; and 8. Optum® de-identified Electronic Health Record Dataset (OPTUM_EHR_US), which covers more than 103 million patients and over 7,000 hospitals and clinics across the US.

The claims-based databases were the Japan Medical Data Center (JMDC_JAPAN) and four US administrative claims databases: IBM MarketScan Commercial Claims and Encounters Database (CCAЕ_US), IBM MarketScan Medicare Supplemental and Coordination of Benefits Database (MDCR_US), IBM MarketScan Multi-State Medicaid Database (MDCD_US), Optum® De-Identified Clinformatics® Data Mart Database – Socio-Economic Status (OPTUM_SES_US).

A detailed description of the databases can be found in Appendix Table 1.

All datasets were previously mapped to the Observational Medical Outcomes Partnership common data model, which is maintained by the Observational Health Data Sciences and Informatics (OHDSI) network. The analysis code could therefore be distributed across all contributing centers without sharing patient-level data.[7,8]

Population/study participants

In our primary analysis, we defined the target at-risk population as people who were observed on 1 January 2017, 1 January 2018, or 1 January 2019 and were observed for at least 365 days before this observation date. We defined 1 January each year as the index date.

Events of interest

The events of interest in this study were the AESIs that might need evaluation following COVID-19 vaccination. This outcome list was developed primarily based on the “Background Rates of Adverse Events of Special Interest for COVID-19 Vaccine Safety Monitoring” protocol published by the FDA Center for Biologics Evaluation and Research, the prioritised COVID-19 vaccine AESI list by the Brighton Collaboration, and other previous studies.[4,9] Fifteen events were included: non-hemorrhagic stroke, hemorrhagic stroke, acute myocardial infarction, deep vein thrombosis, pulmonary embolism, anaphylaxis, Bell’s palsy, myocarditis/pericarditis, narcolepsy, appendicitis, immune thrombocytopenia, disseminated intravascular coagulation, encephalomyelitis (including acute disseminated encephalomyelitis), Guillain-Barre syndrome, and transverse myelitis.[4]

Events were identified by condition occurrence records (e.g., diagnosis codes from claims or diagnosis codes and problem lists from electronic health records). Encephalomyelitis, non-

1
2
3 hemorrhagic stroke, hemorrhagic stroke, and acute myocardial infarction definitions also
4 required the record to occur within an inpatient setting (any position), while the Guillain-Barre
5 syndrome definition required the condition to be recorded in an inpatient setting in the
6 primary position.
7

8
9 Qualifying events could not be previously observed in a 'clean window' period before the
10 index date. In keeping with the FDA protocol, we applied a clean window of 365 days for all
11 events except anaphylaxis (30 days) and facial nerve palsy and encephalomyelitis (183 days)
12 [4]. The full specifications of all phenotype definitions, including source codes and standard
13 concepts, are available in Appendix Tables 2 and 3.
14

15
16 As the CPRD-GOLD (UK), IQVIA (France, Germany, and Australia), and IPCI (the Netherlands)
17 databases only included primary care data, we did not use them for events whose definition
18 required an inpatient diagnosis.
19

20 Analysis

21 We defined the time-at-risk as a 365-day period following the index date. People contributed
22 time-at-risk from 1 January to 31 December for each qualifying year in 2017 to 2019, but time
23 was censored during the clean window following an event and at the end of a person's
24 observation period. One person could contribute more than one event, with outcome-specific
25 pre-specified clean periods of 30 to 365 days used to avoid duplicate counts.
26
27

28 Incidence rates were estimated as the total number of events divided by the person-time at
29 risk per 100,000 person-years. We calculated the age-by-sex specific incidence rates in each
30 database and report all rates where the event counts exceeded a minimum cell count of 5.
31 Age was calculated as year of index date minus year of birth and was partitioned into eight
32 mutually exclusive age groups: 1-5 years old, 6-17, 18-35, 36-55, 56-64, 65-74, 75-84, and 85
33 years and older. We then pooled age-sex specific rates of each AESI across all databases using
34 random-effects models with the DerSimonian-Laird method to estimate between-database
35 variance[10]. We estimated 95% predicted intervals (95% confidence intervals) using the R
36 package 'meta'. [11]
37
38

39
40 Meta-analytic age and sex-specific rates were classified using the World Health Organization
41 Council for International Organizations of Medical Sciences (CIOMS) thresholds: very common
42 ($\geq 1/10$), common ($< 1/10$ to $\geq 1/100$), uncommon ($< 1/100$ to $\geq 1/1,000$), rare ($< 1/1,000$ to
43 $\geq 1/10,000$), and very rare ($< 1/10,000$). [12]

RESULTS

From 13 databases, 126,661,070 people contributed 227,043,370 person-years of follow-up. Each database captured important different population demographics, as shown in Table 1, and collectively represented all age and sex subgroups from eight countries.

Table 2 summarises the incidence rates of the 15 AESIs, stratified by age and sex, based on prediction intervals from a meta-analysis of the database estimates. Each age/sex subgroup was also classified using the CIOMS adverse event frequency system (very common, common, uncommon, rare, or very rare). The incidence of several outcomes varied substantially by age. For example, acute myocardial infarction was very rare (<1/10,000) in women under 35 years, rare (1/1,000 to 1/10,000) in women aged 35 to 54 years, uncommon (1/100 to 1/1,000) in both men and women aged 55 to 84 years, and common (1/10 to 1/100) in men and women aged 85 years and older. For both men and women, deep vein thrombosis was rare in those under 18 years, uncommon in those aged 35 to 84 years, and common in those 85 years and older. Women aged 18 to 34 years had a higher rate of deep vein thrombosis than men of the same age.

The AESIs studied spanned the continuum of possible frequencies. Non-hemorrhagic stroke, acute myocardial infarction, and deep vein thrombosis were all common in those aged 85 years and older and uncommon in those aged 55 to 74 years. Anaphylaxis, Bell's palsy, appendicitis, and immune thrombocytopenia were largely rare in all age groups, although appendicitis was uncommon in those aged 6 to 34 years. Guillain-Barre syndrome and transverse myelitis were very rare in nearly all subgroups.

The prediction intervals for each age-sex subgroup were notably wide, reflecting the substantial population-level heterogeneity observed across sources. Figure 1 shows the database-specific incidence rates that were used to calculate the meta-analytic estimates. The rates recorded for deep vein thrombosis highlight this variation. For women aged 35 to 54 years, the incidence rates ranged from 159/100,000 person-years in Spain (SIDIAP) to 866/100,000 person-years in the US (MDCD). We obtained 13 database estimates for the incidence in women aged 65 to 74 years, ranging from 387/100,000 to 1,443/100,000 person-years. Eight databases gave rates under 650/100,000 person-years (CPRD-GOLD in the UK; CUIMC in the US; IPCI in the Netherlands; IQVIA in Australia, France, and Germany; JMDC in Japan; and SIDIAP-H in Spain), while three databases gave rates more than twice as high, at over 1,300/100,000 person-years (MDCD, MDCR, and OPTUM-SES in the US). Among women aged 75 to 84 years, the lowest incidence rate was 585/100,000 person-years (CPRD-GOLD in the UK) and the highest was 2,167/100,000 person-years (MDCR in the US). We could not find any consistent patterns to explain which databases yielded higher or lower rates across outcomes. Appendix Table 4 lists all database-specific incidence rates.

DISCUSSION

To our knowledge, this is the largest study to date on the descriptive epidemiology of the AESIs prioritised for post-marketing surveillance of COVID-19 vaccines. We report background rates of deep vein thrombosis, pulmonary embolism, stroke, immune thrombocytopenia, and disseminated intravascular coagulation, which are particularly relevance for COVID-19 vaccines given the observed effects of the SARS-COV-2 virus on coagulopathy.[14–17]

1
2
3 Our study provides a comprehensive, detailed assessment of the incidence rates of 15 AESIs
4 across 13 databases, eight countries, and four continents. We found considerable
5 heterogeneity between geographies and databases, suggesting that caution is needed when
6 interpreting the difference between any observed and expected rates. We observed
7 considerable variability with age and sex, emphasizing the need for standardization if
8 background rates are used for surveillance purposes.
9

10
11 Many countries and organizations, such as the US and EU, have passive spontaneous adverse
12 event reporting systems, such as the Vaccine Adverse Event Reporting System (VAERS).
13 However, these systems cannot be used to calculate epidemiological estimates of the burden
14 of disease, including incidence rates, because they lack denominators, which are the total
15 number of persons or person-times being observed.[18,19] Background incidence rates have
16 been used to estimate the expected number of events in the general population.[3,19] They
17 are often obtained from the literature, but methods, case and population definitions, data,
18 and calendar time can vary across publications. In contrast, we calculated all of the presented
19 estimates using precisely the same setting and common analysis procedures, phenotyping
20 algorithms, and data model. However, we still found substantial heterogeneity, suggesting
21 that using a single overall estimate inadequately represents the true uncertainty around event
22 incidence and may lead to confusion.
23
24
25

26 Population-level heterogeneity across data sources was substantial for all events, even after
27 standardizing outcome definitions and stratifying by age and sex. While potentially concerning
28 when seen together in one analysis, our findings are consistent with what has been observed
29 in the literature. For example, in our study, the meta-analysis estimated incidence rates of
30 transverse myelitis ranging from 1 to 4 per 100,000 person-years depend on age-sex strata.
31 Previous studies have reported overall incidence rates of transverse myelitis ranging from 0.4
32 to 4.6 per 100,000 person-years.[19,20] The rates of Bell's palsy among those over 65 years
33 old has ranged from 4.6 per 100,000 person-years in European data to 174 per 100,000
34 person-years in US data.[21,22] Rates of narcolepsy from 1 to over 30 per 100,000 person-
35 years have been reported among those aged 25 to 44 years.[21,22] Recently reported data
36 from the ACCESS project also showed similar magnitudes of heterogeneity in background
37 rates.[5] This heterogeneity needs to be taken into account when comparing rates across
38 populations.
39
40
41

42 Most of the studied outcomes also had considerable within-source patient-level
43 heterogeneity that followed age and sex patterns. For example, rates of cardiovascular
44 diseases such as acute myocardial infarction, hemorrhagic and non-hemorrhagic stroke, deep
45 vein thrombosis, and pulmonary embolism increased with age. The incidence of Guillain-Barre
46 syndrome and Bell's palsy also increased with age. Narcolepsy and appendicitis were more
47 common in younger populations. The patterns observed in our study were generally
48 comparable with previous reports.[2,3,21–25] Stratification by age and sex or standardization
49 are likely to be useful analytic strategies to reduce confounding when comparing incidence
50 rates across populations. However, the magnitude of heterogeneity across sources within age-
51 sex subgroups suggest that residual patient-level differences will remain, including the
52 differences in the distributions of other risk factors such as comorbidities and medication use.
53
54
55

56 Comparing published results can be limited by differing study methodology, including the
57 time-at-risk definition, study period, event definitions, population coverage, calendar year,
58 and geographic location.[26] Different subgroup definitions also make direct comparison
59
60

1
2
3 difficult. For example, previous studies of Guillain-Barre syndrome have used age strata that
4 do not fully overlap with each other.[2,5,21,25,27,28] In contrast, because we applied the
5 same definitions, data model, and analysis to all of the databases within our study, the
6 heterogeneity observed cannot be attributed to analysis variability. Instead, it may have been
7 due to differences in the underlying populations, healthcare systems, and data capture
8 processes. Although some variability may have been due to systematic error, selection bias or
9 differential outcome measurement error between databases, some may reflect true
10 population differences such as socioeconomic status and comorbidities.
11
12

13
14 As we observed notable differences between age, sex, and databases, caution should be
15 exercised when using incidence rates as a basis for comparison. Comparisons between
16 incidence rates from different sources may be subject to substantial systematic error. We
17 observed large variations between electronic health records and claims data sources when
18 using the same analysis and outcome definitions. Comparisons with rates derived from
19 randomised trials or spontaneous reporting data may have even greater variability. If
20 observational databases are to be used to inform safety surveillance activities, within-
21 database analyses (such as self-controlled case designs or propensity-score adjusted
22 comparative cohort designs) may help reduce study bias for any given comparison.
23 Demonstrating consistent effects across databases may further strengthen confidence in
24 results. If observational data are used to derive historical 'expected' rates and compared
25 against observed rates of events from another source, then the uncertainty in the background
26 rate must be appropriately integrated to avoid misleading conclusions.
27
28
29

30
31 Our large number of participating databases, geographical coverage, and sizable study
32 population allowed us to provide a comprehensive assessment of the background incidence
33 rates across different healthcare systems and regions across the globe. Our study took
34 advantage of the Observational Medical Outcomes Partnership common data model, which
35 allowed us to use the same study design and analytical code and to gather results from
36 participating data partners rapidly and without transferring patient-level data. All outcome
37 definitions, clinical codes and phenotype algorithms have been made open source and are
38 available online for review and to maximise reproducibility and reuse.
39

40
41 The primary limitation of this study is that all outcomes may have been subject to
42 measurement error. As the outcome definitions were based on the presence of specific
43 diagnostic codes and were not validated further, they may have had imperfect sensitivity or
44 specificity. The analysis relied on data from 2017 to 2019 using a target population of all
45 people in each database with >365 days of observation indexed on 1 January, 365 days' time-
46 at-risk, and outcome-specific clean windows to allow for recurrent events. The impact of these
47 design decisions should be explored further.
48

50 51 **CONCLUSION**

52
53 This study comprehensively assessed the descriptive epidemiology of potential AESIs for
54 COVID-19 vaccines. It highlighted the wide range of adverse effects being monitored, from
55 very rare neurological disorders to more common thromboembolic conditions. We reported
56 large variations in the observable rates of AESI by age group and sex, demonstrating the need
57 to account for stratification or standardization before using background rates for safety
58 surveillance. We also found significant population-level heterogeneity in AESI rates between

Acknowledgement

This work was partially funded by the UK National Institute of Health Research (NIHR), European Medicines Agency, European Health Data & Evidence Network (EHDEN), US Food and Drug Administration CBER BEST Initiative (75F40120D00039), and US National Library of Medicine (R01 LM006910). EHDEN has received funding from the Innovative Medicines Initiative 2 Joint Undertaking (JU) under grant agreement No 806968. The JU receives support from the European Union's Horizon 2020 research and innovation program and EFPIA.

DPA receives funding from NIHR in the form of a Senior Research Fellowship and the Oxford NIHR Biomedical Research Centre. XL receives the Clarendon Fund and Brasenose College Scholarship (University of Oxford) to support her DPhil study.

We acknowledge English language editing by Dr Jennifer A. de Beyer, Centre for Statistics in Medicine, University of Oxford.

Contributors

DAP, XL, PR, and GH conceived the idea of this study. XL, AO, GH, PR, and DAP were responsible for interpreting the results and writing the manuscript. RM, AZ, GR, and AS were responsible for implementing the study. XL, AO, PR, RM, KV, PRR, TDS, and MAS Contributed to the study execution (Data holders). XL, AO, GH, and PR Contributed to the study design. All the co-authors contributed to writing the manuscript. All authors approved the final version and had final responsibility for the decision to submit for publication.

Copyright/license for publication

The Corresponding Author has the right to grant on behalf of all authors and does grant on behalf of all authors, a worldwide licence to the Publishers and its licensees in perpetuity, in all forms, formats and media (whether known now or created in the future), to i) publish, reproduce, distribute, display and store the Contribution, ii) translate the Contribution into other languages, create adaptations, reprints, include within collections and create summaries, extracts and/or, abstracts of the Contribution, iii) create any other derivative work(s) based on the Contribution, iv) to exploit all subsidiary rights in the Contribution, v) the inclusion of electronic links from the Contribution to third party material where-ever it may be located; and, vi) licence any third party to do any or all of the above.

Declaration of interests

All authors have completed the ICMJE disclosure form at <http://www.icmje.org/disclosure-of-interest/>. DPA's research group has received research grants from the European Medicines Agency, from the Innovative Medicines Initiative, from Amgen, Chiesi, and from UCB Biopharma; and consultancy or speaker fees from Astellas, Amgen and UCB Biopharma. GH and AO receive funding from the US National Institutes of Health and the US Food and Drug Administration. KV and PR work for a research group who receives/received unconditional research grants from Yamanouchi, Pfizer-Boehringer Ingelheim, Novartis, GSK, Amgen, Chiesi none of which relates to the content of this paper. PBR, RM, AS, GR, AGS are employee of Janssen Research and Development, and shareholder in Johnson & Johnson. MAS receives grants and contracts from the US Food & Drug Administration and the US Department of Veterans Affairs within the scope of this research, and grants and contracts from the US National Institutes of Health, IQVIA and Private Health Management outside the scope of this research. Description
Anonymized patient records of more than 6 million patients in Australia collected from Patient Management software used by GPs during an office visit to document patients' clinical records.
Anonymized patient records of 7.8 million patients in France collected from Patient Management software used by GPs and select specialists during an office visit to document patients' clinical records
IQVIA DA Germany is collected from extracts of patient management software used by GPs and specialists practicing in ambulatory care settings. Data coverage includes more than 34M distinct person records out of a total population of 80M (42.5%) in the country and collected from 2,734 providers. Dates of service include from 1992 through March 2020.
Japan Medical Data Center (JMDC) database consists of data from 60 society-managed health insurance plans covering workers aged 18 to 65 and their dependents (children younger than 18 years old and elderly people older than 65 years old). JMDC data includes membership status of the insured people and claims data provided by insurers under contract (e.g. patient-level demographic information, inpatient and outpatient data inclusive of diagnosis and procedures,
The Integrated Primary Care Information (IPCI) database is a Dutch database containing the medical records of more than 2.5 million patients provided by more than 600 GPs geographically spread over the Netherlands. In the Netherlands, all citizens are registered with a GP practice which acts as a gatekeeper in a two-way exchange of information with secondary care
Optum® de-identified Electronic Health Record Dataset is derived from dozens of healthcare provider organizations in the United States (that include more than 700 hospitals and 7,000 Clinics treating more than 103 million patients) receiving care in the United States. The medical record data includes clinical information, inclusive of prescriptions as prescribed and administered, lab results, vital signs, body measurements, diagnoses, procedures, and information derived from clinical Notes using Natural Language Processing (NLP).
Optum® De-Identified Clinformatics® Data Mart Database is an adjudicated administrative health claims database for members with private health insurance, who are fully insured in commercial plans or Medicare Advantage. The population is primarily representative of US commercial claims patients (0-65 years old) with some Medicare (65+ years old) however ages are capped at 90 years. It includes data captured from administrative claims processed from inpatient and outpatient medical services and prescriptions as dispensed, as well as results for outpatient lab tests processed by large national lab vendors who participate in data exchange with Optum. Optum SES provides socio-economic status for members with both medical and pharmacy coverage and location
IBM MarketScan Medicare Supplemental and Coordination of Benefits Database (MDCR) represents health services of retirees in the United States with primary or Medicare supplemental coverage through privately insured fee-for-service, point-of-service, or capitated health plans. These data include adjudicated health insurance claims (e.g. inpatient, outpatient, and outpatient pharmacy). Additionally, it captures laboratory tests for a subset of the covered lives.

1
2 IBM MarketScan Multi-State Medicaid Database (MDCD) contains adjudicated
3 US health insurance claims for Medicaid enrollees from multiple states and
4 includes hospital discharge diagnoses, outpatient diagnoses and procedures, and
5 outpatient pharmacy claims as well as ethnicity and Medicare eligibility.

6 Members maintain their same identifier even if they leave the system for a
7 brief period; however, the dataset lacks lab data.

8
9 IBM MarketScan Commercial Claims and Encounters Database (CCAE) is a US
10 employer-based private-payer administrative claims database. The data include
11 adjudicated health insurance claims (e.g. inpatient, outpatient, and outpatient
12 pharmacy) as well as enrollment data from large employers and health plans who
13 provide private healthcare coverage to employees, their spouses, and dependents.
14 Additionally, it captures laboratory tests for a subset of the covered lives. This
15 administrative claims database includes a variety of fee-for-service, preferred
16 provider organizations, and capitated health plans.

17
18
19 The Clinical Practice Research Datalink (CPRD) is a governmental, not-for-
20 profit research service, jointly funded by the NHS National Institute for Health
21 Research (NIHR) and the Medicines and Healthcare products Regulatory Agency
22 (MHRA), a part of the Department of Health, United Kingdom (UK). CPRD
23 consists of data collected from UK primary care for all ages. This includes
24 conditions, observations, measurements, and procedures that the general
25 practitioner is made aware of in addition to any prescriptions as prescribed by
26 the general practitioner. In addition to primary care, there are also linked
27 secondary care records for a small number of people. The major data elements
28 contained within this database are outpatient prescriptions given by the general
29 practitioner (coded with Multilex codes) and outpatient clinical, referral,
30 immunization or test events that the general practitioner knows about (coded in
31 Read or ICD10 or LOINC codes). The database also contains the patients' year

34 The clinical data warehouse of New York-Presbyterian Hospital/Columbia
35 University Irving Medical Center, New York, NY, based on its current and
36 previous electronic health record systems, with data spanning over 30 years and
37 including over 6 million patients

38
39
40 The Information System for Research in Primary Care (SIDIAP;
41 www.sidiap.org) is a primary care records database from Catalonia, North-East
42 Spain. The SIDIAP-H subset of the database includes around 2 million people
43 out of the total 7 million in SIDIAP that are registered in primary care practices
44 with linked hospital inpatient data available as obtained from the Catalan
45 Institute of Health hospitals. Healthcare is universal and tax-payer funded in the
46 region, and primary care physicians are gatekeepers for all care and responsible
47 for repeat prescriptions.
